LM3550 5-A Super-Capacitor Flash LED Driver

Technical [Documents](http://www.ti.com/product/LM3550?dcmp=dsproject&hqs=td&#doctype2)

1 Features

- Up to 5 A Flash Current
- 4 Selectable Super-Capacitor Charge Voltage Levels (4.5 V, 5 V, 5.3 V, Optimized)
- Adjustable Torch Current (60 mA to 200 mA)
- Ambient Light or LED Thermal Sensing With Current Scaleback
- • Dedicated Indicator LED Current Source
- No Inductor Required
- Programmable Flash Pulse Duration, and Torch and Flash Currents via I ²C-Compatible Interface
- • True Shutdown (LED Disconnect)
- Flash Timeout Protection
- Low Profile 20-Pin UQFN Package $(3 \text{ mm} \times 2.5 \text{ mm} \times 0.8 \text{ mm})$

2 Applications

- Digital Still Camera
- • Voltage Rail Management
- Fire Alarm Notification
- **Emergency Strobe Lighting**
- Intruder Alert Notification
- • Barcode Scanner
- • Handheld Data Terminal

3 Description

Tools & **[Software](http://www.ti.com/product/LM3550?dcmp=dsproject&hqs=sw&#desKit)**

The LM3550 device is a low-noise, switchedcapacitor DC-DC converter designed to operate as a current-limited and adjustable (up to 5.3 V) supercapacitor charger. The LM3550 features userselectable termination voltages and provides one adjustable constant current output (up to 200 mA) and one NFET controller ideal for driving one or more high-current LEDs in a high-power flash mode or a low-power torch mode.

Support & **[Community](http://www.ti.com/product/LM3550?dcmp=dsproject&hqs=support&#community)**

22

The LED current and flash pulse duration of the LM3550 can be programmed via an l²C-compatible interface. The STROBE pin allows the flash to be toggled via a flash-enable signal from a controller or camera module. The EOC pin sinks current when the output voltage reaches 95% of the final value.

The ALD/TEMP input pin allows either a light sensor to adjust the flash-current level based on the ambient light conditions, or it allows for overtemperature detection and protection of the LED during highpower operation or high ambient-temperature conditions.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted) $(1)(2)(3)$

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *[Recommended](#page-3-3) Operating [Conditions](#page-3-3)*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

All voltages are with respect to the potential at the GND pin.

(3) If Military/Aerospace specified devices are required, contact the Texas Instruments Sales Office/ Distributors for availability and specifications.

6.2 ESD Ratings

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) The LED pin has a machine model ESD rating of 150 V.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

(1) All voltages are with respect to the potential at the GND pin.

6.4 Thermal Information

(1) For more information about traditional and new thermal metrics, see the *[Semiconductor](http://www.ti.com/lit/pdf/spra953) and IC Package Thermal Metrics* application report.

⁽⁴⁾ Internal thermal shutdown circuitry protects the device from permanent damage. Thermal shutdown engages at $T_J = 145^{\circ}C$ (typical) and disengages at $T_J = 125^{\circ}C$ (typical). The thermal shutdown is specified by design.

6.5 Electrical Characteristics

Typical imits are for T_J = 25°C; minimum and maximum limits apply over the full ambient junction temperature range (−30°C ≤ T_A ≤ 85°C). Unless otherwise noted, specifications apply to *Typical [Application](#page-0-8)* with: : V_{IN} = 3.6 V, C_{IN} = 4.7 µF, C_{OUT} = 2.2 μ F, C₁ = C₂ = 1 μ F.⁽¹⁾⁽²⁾

(1) All voltages are with respect to the potential at the GND pin.

(2) Junction-to-ambient thermal resistance $(R_{0,J}A)$ is taken from a thermal modeling result, performed under the conditions and guidelines set forth in the JEDEC standard JESD51-7. The test board is a 4-layer FR-4 board measuring 102 mm \times 76 mm \times 1.6 mm with a 2 \times 1 array of thermal vias. The ground plane on the board is 50 mm x 50 mm. Thickness of copper layers are 36 µm/18 µm/18 µm/36 µm (1.5oz/1oz/1oz/1.5oz). Ambient temperature in simulation is 22°C, still air. Power dissipation is 1 W.

(3) Minimum (MIN) and maximum (MAX) limits are specified by design, test, or statistical analysis. Typical (TYP) numbers are not ensured, but do represent the most likely norm. Unless otherwise specified, conditions for TYP specifications are: $V_{IN} = 3.6$ V and $T_A = 25$ °C.

7 Detailed Description

7.1 Overview

The LM3550 is a super-capacitor charger and high-current-flash controller based upon a switched-capacitor boost converter. On the charging end of the application, the LM3550 has a 534 mA (typical) input current limit that prevents the part from drawing an excessive current when the super-capacitor voltage is below the target charge voltage. During the charge phase the LM3550 runs in current limit and adaptively change gains (1×, 1.5×, 2×) until the super-capacitor reaches its target charge voltage. Integrated into the LM3550 is an external NFET controller that allows the flash current drawn from the super-capacitor to remain regulated throughout the flash cycle. Flash timing and current level can be changed through the I²C-compatible interface.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 STROBE Pin

The STROBE pin on the LM3550 provides an external method of flash triggering. This means a direct connection between a controller or camera/imager and the LM3550 device can be made, avoiding any latency added due to communication delays. The STROBE pin can be configured to be rising-edge sensitive (default) or level sensitive. In the rising-edge sensitive mode, the flash duration is controlled internally and uses the value stored in the FLASH duration bits (Options Control Register bits 3:0) to determine the pulse length. If level sensitive mode is selected (Options Control Register bit $7 = 1$), the flash-pulse duration can be controlled externally. In this mode, when the STROBE pin is high, the flash remains on as long as the duration does not exceed the value stored in the FLASH duration control bits. If the timing does exceed the internal flash-duration value, the LM3550 automatically disables the flash current.

Feature Description (continued)

7.3.2 End-of-Charge Pin (EOC)

The EOC pin provides an external flag alerting the microcontroller/microprocessor that the super-capacitor has reached the end of charging. When the super-capacitor has reached the desired end-of-charge level, the EOC pin transitions from its default state (logic 1) to the EOC state (logic 0). The EOC pin utilizes an open-drain driver that allows the EOC logic levels to be compatible with many of the common controller input/output (I/O) levels. Connecting a resistor between the system I/O supply and the EOC pin on the LM3550 ensures the proper voltage levels are utilized.

The state of the EOC pin can change during a flash event, or any other event whenever the super-capacitor voltage drops below 95% of the target charge voltage.

7.3.3 ALD/TEMP Pin

The ALD/TEMP pin allows the LM3550 to monitor the ambient light or ambient temperature and adjust the flash current through the LED/LEDs without requiring the microcontroller/microprocessor to issue commands through the control interface.

For ambient light detection, a reverse-biased photosensor/diode and a resistor are required. For ambient temperature sensing, a negative temperature coefficient (NTC) thermistor and a resistor are required. Internal to the LM3550 are two comparators (based on a 1-V reference) connected to the ALD/TEMP pin that provide three user-selectable regions of flash current adjustment. The trip-point thresholds are selectable in the ALD/TEMP Sense High and Low Registers.

If the ambient light or ambient temperature are sufficiently low (LM3550 in low region) the full-scale flash current is allowed. As the lighting conditions or temperature increase, the LM3550 ALD/TEMP detection circuit transitions to the second level that limits the flash current to 70% or the full-scale value. For conditions where a flash is not required (ambient detection) or if the ambient temperature is too high to flash safely, placing the ALD/TEMP circuit in the high-detection level, the LM3550 prevents a flash event from occurring. The functionality of the ALD/TEMP pin can be enabled or disabled through General Purpose Register (bit 6). These macro-functions, when enabled, off-load the microcontroller/microprocessor and provide significant system-power savings.

To help filter out the 50 to 60 Hz noise caused by indoor lighting, TI recommends a 1-µF ceramic capacitor tied between the ALD/TEMP pin and GND.

7.3.4 IND Pin

The Indicator pin (IND) consists of a current source that is capable of driving a red indicator LED with 5 mA of drive current. This indicator LED can be turned on and off by toggling bit 7 in the General Purpose Register.

7.3.5 BAL Pin

The Balance pin (BAL), when connected to a super-capacitor (if needed), regulates the two sections of the super-capacitor so that voltage on either cell is equal to $\frac{1}{2}$ the output voltage. This ensures that an overvoltage condition on either capacitor section does not occur.

7.3.6 Super-Capacitor Charging Time

The time it takes the LM3550 to charge a super-capacitor from 0 V to the target voltage is highly dependent on the input voltage, output-voltage target, and super-capacitor capacitance value.

- The LM3550 up a capacitor faster if the target output voltage is lower and slower if the target output voltage is higher. For a given charge profile, a up a capacitor faster with higher input voltage and slower with lower input voltages. This is due to the LM3550 staying in the lower gains for longer periods of time.
- The LM3550 charges up a capacitor faster if the target output voltage is lower and slower if the target output voltage is higher. For a given charge profile, a lower capacitor voltage is reached faster than a higher voltage level.
- The LM3550 charges up a capacitor having a lower capacitance value faster than a capacitor having a higher capacitance level.

Feature Description (continued)

(1) Optimal Mode Flash = 2 LEDs at 3 A (1.5 A each) for 48 ms. Super-capacitor part number: TDK EDLC272020-501-2F-50.

7.3.7 Super-Capacitor Voltage Profile

When a constant load current is drawn from the charged super-capacitor, the voltage on the capacitor changes. The capacitor ESR and capacitance both affect the discharge profile.

At the beginning of the flash (t_{START}), the super-capacitor voltage drops due to the ESR of the super-capacitor. The magnitude of the drop is equal to the flash current (I_{FLABH}) multiplied by the ESR (R_{ESR}).

$$
V_{ESR} = I_{FLASH} \times R_{ESR}
$$
 (1)

Once the initial voltage drop occurs (V_{ESR}) the super-capacitor voltage decays at a constant rate until the flash ends (t_{FINISH}). The voltage droop (V_{DROOP}) during the flash event is equal to flash current (I_{FLASH}) multiplied by the flash duration ($t_{F|ASH}$) divided by the capacitance value of the super-capacitor (C_{SC}).

$$
V_{\text{DROOP}} = (I_{\text{FLASH}} \times t_{\text{FLASH}}) / C_{\text{SC}} \tag{2}
$$

After the flash event has finished, the voltage on the super-capacitor increases due to the absence of current flowing through the ESR of the super-capacitor. This step-up is equal to

$$
V_{ESR} = I_{FLASH} \times R_{ESR} \tag{3}
$$

7.3.8 Peak Flash Current

To set the peak flash current controlled by the LM3550, a current setting resistor must be placed between the source of the current source and ground (FB to GND). The LM3550 regulates the voltage across the resistor to a value between 100 mV and 30 mV depending on the setting in the Current Control Register. Using the 100 mV setting, the peak flash current can be found using Equation 4:

$$
I_{FLASH} = V_{FB} / R_{SENSE}
$$
 (4)

The LM3550 provides eight feedback voltage levels allowing eight different current settings. The current ranges from 100% of full-scale (100 mV setting) down to 30% of full-scale (30 mV setting) in 10% steps.

7.3.9 Maximum Flash Duration

Several factors determine the maximum achievable flash pulse duration. The flash current magnitude, feedback voltage, R_{DSON} of the current source FET, super-capacitor capacitance (C_{SC}), super-capacitor ESR (R_{ESR}) and super-capacitor charge voltage (V_{CAP}) determine the ability of the device to regulate the flash current for a given amount of time.

 t_{FLASH} (maximum) = $(C_{SC} \times V_{DROOP}) / I_{FLASH}$

where

 $V_{\text{DROOP}} = V_{\text{CAP}} - V_{\text{LED}} - [I_{\text{FLASH}} \times (R_{\text{ESR}} + R_{\text{DSON}} + \{R_{\text{BAL}}/N)\}] - V_{\text{FB}}$

Charger

VBAT

• N = number of flash LEDs (5)

Example:

If $V_{CAP} = 5.3$ V, $V_{LED} = 4$ V (at 1.5 A), I_{FLASH} (total) = 3 A, $C_{SC} = 0.5$ F, $R_{ESR} = 50$ mΩ, $R_{DSON} = 40$ mΩ, V_{FB} = 100 mV, and R_{BAL} = 75 m Ω , then V_{DROOP} = 0.82 V and t_{FLASH} (maximum) = 136 ms.

7.4 Device Functional Modes

7.4.1 State Machine Description

Figure 38. Default State Diagram

7.4.1.1 Basic Description

The state machine for the LM3550 involves five different states: shutdown, torch, charge, charge and torch, and flash.

The shutdown state, or standby state, places the LM3550 in a low-power mode that typically draws 1.8 µA of current from the power supply.

The torch state charges the super-capacitor up to $V_{LED} + V_{TREG}$ ($V_{TREG} \approx 300$ mV) and utilizes the internal current sink to drive the flash LEDs with a current up to 200 mA.

The charge state places the LM3550 into a dedicated charge mode that provides the fastest means of charging the super-capacitor up to the target level $(4.5 V, 5 V, 5.3 V$ or optimal).

The charge and torch state combines the functionality of both the torch state and charge state. This state allows the flash LEDs to be on during the charging of the super-capacitor. During the initial charging, the torch current is limited to 60 mA to allow the majority of the output current to be utilized in the super-capacitor charging. Once the target capacitor voltage is reached, the torch-current levels become fully adjustable.

The Flash state is responsible for driving the flash LEDs at the desired flash current. This state can be entered either through I²C-controlled event or through an external strobe event.

7.4.1.2 Shutdown State

The shutdown state is the default power-up state. The LM3550 enters the shutdown state when the STROBE pin is held low without a flash event occurring, and when the flash, torch, and charge bits in the General Purpose Register are equal to 0.

7.4.1.3 Torch State

The torch state of the LM3550 provides the flash LED / LEDs with a constant current level that is safe for continuous operation. This state is useful in low light conditions when an imager is placed in movie or video mode. The torch state is enabled when the torch bit in the General Purpose Register is set to a 1 and the flash and charge bits are set to 0. The desired torch current level (8 total levels between 60 mA and 200 mA) is set in the Current Control Register.

Enabling the torch bit starts up the LM3550 and begin charging the capacitor. Before a torch event can occur, the super-capacitor must be charged to a voltage greater than 3 V. Once the super-capacitor reaches a voltage of 3 V, the LED− pin begins sinking current. In order for the torch current to be properly regulated, the super-capacitor must be charged up to a value that is greater than $V_{\text{LED}} + V_{\text{TRFG}}$ (V_{TREG} \approx 300 mV).

When in the torch state, the LM3550 regulates the proper output voltage (either 3 V or V_{LED} + V_{REG}) utilizing a pulsed regulation scheme (PFM). During this mode, the device operate in current limit until the output voltage reaches the target level. At that point, the charge-pump turns off, and the super-capacitor supplies the load. Once the super-capacitor voltage drops below the turnon threshold due to the loading caused by the torch current, the charge-pump turns on again and re-charges the super-capacitor.

7.4.1.4 Charge State

The charge state of the LM3550 provides the fastest charge time when compared to the other states of operation. In this state, the user has the option of charging the super-capacitor to a voltage equal to 4.5 V, 5 V, 5.3 V or to an optimal voltage. The charge state is enabled through the I^2C interface by setting the charge bit to a 1 and setting the flash and torch Bits to a 0 in the General Purpose Register. The charge voltage is selectable by setting the two charge-mode bits (CM1 and CM0) also found in the General Purpose Register.

Depending on the input voltage and output voltage conditions, the LM3550 delivers different charge currents to the super-capacitor. Charge current is dependent on the charge-pump gain.

Figure 39. Charge Current vs Output Voltage

7.4.1.4.1 Fixed-Voltage-Charge Mode

During the charge state, the LM3550 operates in current limit until the target voltage is reached. For the 4.5 V, 5 V and 5.3 V charge modes, the LM3550 operates in a constant-frequency mode once the target voltage is reached for load currents greater than 60 mA. This allows the LM3550 to draw only the required current from the power source when the load current is less than the maximum. When the average output current exceeds the maximum of the LM3550, the device returns to the current limited operation until the target voltage is reached. If the output current is less than 60 mA, the LM3550 operates in a PFM-burst mode.

7.4.1.4.2 Optimal Charge Mode

For the optimal charge mode, the current-limited, pulsed-regulation scheme (PFM) is used to maintain the target voltage. In optimal charge mode, the LM3550 charges the super-capacitor to a level that is required to sustain a flash for a given period of time. optimal charge mode compensates for variations in LED forward voltage and super-capacitor ESR by charging the capacitor to an optimal voltage that minimizes the power dissipated in the external current source during the flash. The user must calculate the required overhead voltage and select this value in the Options Control Register. For more information regarding the optimal charge mode, see the *Application and [Implementation](#page-27-0)* description.

NOTE

When the LM3550 is placed into optimal charge mode, the flash LEDs begin to glow once the super-capacitor voltage exceeds 3 V. The LEDs continue to glow until the device is placed into shutdown, into the flash state, or into one of the fixed-voltage charge modes.

7.4.1.5 Torch and Charge State

The torch and charge state provides the ability to utilize the torch functionality while charging to the selected target voltage. The torch and charge state is entered by setting the torch bit and charge bit to a 1 and by setting the flash bit to a 0 in the General Purpose Register. Additionally, the CM1 and CM0 bits can be configured to define the target charge voltage.

During the initial charging of the super-capacitor, the torch functionality is enabled until the capacitor voltage reaches 3 V. Additionally, the torch current is limited to 60 mA until the target voltage is reached. Once the output reaches the target, the current level specified in the Current Control Register is allowed.

In the event that the total output current exceeds the capacitor charge current (I_{CHARGE} = I_{MAX} - I_{TORCH} -I_{EXTERNAL}), causing the super-capacitor to drop below the target voltage, the LM3550 automatically sets the T2 bit in the Current Control Register to a 0, decreasing the torch current.

Figure 40. Torch Current Diagram

7.4.1.6 Flash State

When entered, the flash state of the LM3550 device delivers a high-current burst of current to the flash LEDs. To enter the flash state, the flash bit in the General Purpose Register must be set to a 1 or the STROBE pin must be pulled high (edge or level sensitive). The flash duration and current level are user adjustable via the I²C interface (F2-F0 in current control and FD3-FD0 in options).

By default, a flash does not occur if the super-capacitor is not fully charged (that is, the end-of-charge flag (EOC pin) must transition low). If the flash state was entered via the I²C interface (flash bit = 1), the LM3550 automatically resets the flash bit and the torch bit to 0 upon completion of the flash. Additionally, after the flash event has occurred, the LM3550 returns to the charge state/mode that was in operation before the flash event with the exception of optimal charge mode. (If optimal charge mode was used before a flash, all charging is halted after the flash.)

7.4.1.7 EOC Functionality

The EOC pin of the device provides an indicator alerting the controller that the super-capacitor has reached its target voltage. The EOC pin transitions low once the capacitor reaches 95% of the target voltage for the 4.5 V, 5 V and 5.3 V modes or once the capacitor has reached the optimal charge voltage in optimal charge mode.

During operation, the LM3550 continues to monitor the voltage on the super-capacitor and updates the EOC pin when needed. Any time a mode transition occurs during charge mode or charge and torch mode, the EOC state is re-evaluated.

During torch mode, the \overline{EOC} always indicates a charging state ($\overline{EOC} = 1$).

7.4.1.8 State Diagram FGATE = 1

By default, the LM3550 prevents a flash event from occurring if the super-capacitor has not reached the target voltage ($\overline{EOC} = 0$). In the event that this restriction is not desired, the flash gate bit (\overline{FGATE} in the General Purpose Register) can be set to a 1 disabling the end-of-charge requirement. Setting FGATE to a 1 allows the flash state to be entered at anytime. If the super-capacitor is not charged to the proper voltage before the $\overline{\text{EOC}}$ pin indicates a full charge, the perceived duration and flash level could be lower than desired.

Figure 41. FGATE = 1 State Diagram

7.4.1.9 Optimal Charge Mode vs Fixed Voltage Mode

The LM3550 provides two types of super-capacitor charging modes: fixed voltage and optimal charge.

In fixed voltage mode, the LM3550 charges and regulate the super-capacitor to either 4.5 V, 5 V, or 5.3 V. This mode is useful if the LM3550 is going to be used for both flash and fixed-rail applications (power supply for audio or PA sub-systems).

If the LM3550 is only going to be used as a super-capacitor charger and flash controller, the optimal charge mode provides many advantages over the fixed voltage mode. optimal charge mode charges the super-capacitor to the minimum voltage that is required to sustain a flash pulse compensating for variations in super-capacitor ESR and LED forward voltage due to temperature and process. To properly use the optimal charge mode, the overhead voltage (V_{OH}) must be determined. The overhead voltage is equal to the voltage required to maintain current source regulation (V_{HR}) plus the voltage droop (V_{DROOP}) on the super-capacitor due to the flash event.

$$
V_{OH} = V_{DROOP} + V_{HR} = (I_{FLASH} \times t_{FLASH} / C_{SC}) + V_{FB} + (I_{FLASH} \times R_{DSDON})
$$
\n
$$
(6)
$$

and

 $V_{CAP} = V_{OH} + V_{LED} + [I_{FLASH} \times (R_{ESR} + R_{BAL} / N)]$

where

• N = Number of flash LEDs (7)

Example:

If V_{LED} (peak)= 4.1 V (at 1.5 A), I_{FLASH} (total) = 3 A, C_{SC} = 0.5 F, R_{ESR} = 50 mΩ, R_{DSON} = 40 mΩ, V_{FB} = 100 mV, $R_{BAL} = 75$ m Ω , and t_{FLASH} = 64 ms, then $V_{OH} = 0.604$ V and $V_{CAP} = 4.97$ V.

NOTE

 V_{LED} (peak) is equal to the LED voltage before self-heating occurs. Once current flows through the LED, the LED heats up, and the forward voltage decreases until it reaches a steady-state level. This voltage drop is dependent on the LED and the PCB layout.

Based on this calculation, setting the overhead voltage to 600 mV in the Current Control Register should ensure a regulated 3-A flash pulse over the entire flash duration.

Unlike fixed voltage mode, optimal charge mode adjusts the super-capacitor voltage upon changes in LED forward voltage and variation in super-capacitor ESR, ensuring that the super-capacitor does not charge to a voltage higher than needed. By charging optimally, the LM3550 can potentially charge the super-capacitor to its EOC state faster due to the target voltage being lower, and it helps ease the thermal loading on the current source FET during the flash.

7.4.1.9.1 Optimal Charge Mode vs Fixed Voltage Mode

Peak power dissipation across current source FET

 P_{NFET} (maximum) = I_{FLSH} × (V_{OH} – V_{FB})

where

• Optimal mode = 1.5 W, fixed voltage mode $(5.3 \text{ V}) = 2.4 \text{ W}$ (8)

Average power dissipation across current source FET (64 ms pulse)

 P_{NET} (average) = $I_{\text{FLASH}} \times [V_{\text{OH}} - (V_{\text{DROOP}} \div 2) - V_{\text{FB}}]$

where

Optimal mode = 936 mW, fixed voltage mode $(5.3 \text{ V}) = 1.824 \text{ W}$ (9)

7.5 Programming

7.5.1 I ²C-Compatible Interface

7.5.1.1 Data Validity

The data on SDA line must be stable during the HIGH period of the clock signal (SCL). In other words, the state of the data line can only be changed when SCL is LOW.

Figure 44. Data Validity Diagram

A pullup resistor between VIO (logic power supply) and SDA must be greater than [(VIO - V_{OL}) / 3 mA] to meet the V_{OL} requirement on SDA. Using a larger pullup resistor results in lower switching current with slower edges, while using a smaller pullup resistor results in higher switching currents with faster edges.

7.5.1.2 Start and Stop Conditions

START and STOP conditions classify the beginning and the end of the $I²C$ session. A START condition is defined as SDA signal transitioning from HIGH to LOW while SCL line is HIGH. A STOP condition is defined as the SDA transitioning from LOW to HIGH while SCL is HIGH. The I²C master always generates START and STOP conditions. The I²C bus is considered to be busy after a START condition and free after a STOP condition. During data transmission, the I²C master can generate repeated START conditions. First START and repeated START conditions are equivalent, function-wise. The data on SDA line must be stable during the HIGH period of the clock signal (SCL). In other words, the state of the data line can only be changed when SCL is LOW.

Figure 45. Start and Stop Conditions

Programming (continued)

7.5.1.3 Transferring Data

Every byte put on the SDA line must be eight bits long, with the most significant bit (MSB) being transferred first. Each byte of data has to be followed by an acknowledge bit. The acknowledge-related clock pulse is generated by the master. The master releases the SDA line (HIGH) during the acknowledge clock pulse. The LM3550 pulls down the SDA line during the 9th clock pulse, signifying an acknowledge. The LM3550 generates an acknowledge after each byte has been received.

After the START condition, the I²C master sends a chip address. This address is seven bits long followed by an eighth bit which is a data direction bit (R/W). The LM3550 address is 53h. For the eighth bit, a 0 indicates a WRITE and a 1 indicates a READ. The second byte selects the register to which the data will be written. The third byte contains data to write to the selected register.

id = chip address, 53h for LM3550

7.6.1.4 ALD/TEMP Sense High/Low Registers

Figure 47. ALD/TEMP Sense High Register

MSB	ALD/TEMP Sense Low Register Register Address: 0xD0							
bit7	bit ₆	SL ₅ bit ₅	SL ₄ bit4	SL ₃ bit3	SL ₂ bit2	SL ₁ bit1	SL ₀ bit ₀	

Figure 48. ALD/TEMP Sense Low Register

For ALD/TEMP Sense High and ALD/TEMP sense low, the trip levels are set by [Equation](#page-26-1) 10:

Sense High/Low = $1 \vee \times N / (2^6 - 1)$

where

• N is the decimal equivalent of the value stored in the ALD/TEMP Sense High/Low registers (10)

N_{SENSEHIGH} must be greater than N_{SENSELOW}.

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The LM3550 can drive multiple flash LEDs at currents up to 5 A total. The switched-capacitor boost on the LM3550 eliminates the need of an inductor in the application.

8.2 Typical Application

Copyright © 2016, Texas Instruments Incorporated

Figure 49. LM3550 Typical Application

8.2.1 Design Requirements

For LM3550, use the parameters listed in [Table](#page-27-3) 10.

8.2.2 Detailed Design Procedure

[LM3550](http://www.ti.com/product/lm3550?qgpn=lm3550)

8.2.2.1 Component Selection

8.2.2.1.1 Super-Capacitor

Super-capacitors, or electrochemical double-layer capacitors (EDLC's), have a very high energy density compared to other capacitor types. Most super-capacitors aimed at applications requiring voltages higher than 3V are three-terminal devices (two super-capacitor cells stacked in series). Special care must be taken to ensure that the voltage on each cell of the super-capacitor does not exceed the maximum rating (typically 2.75 V to 2.85 V, depending on the manufacturer). The LM3550 is capable of safely charging super-capacitors of many different capacitances up to a V_{OUT} (maximum) = 5.3 V typical.

The capacitor balance pin (BAL) on the LM3550 ensures that the voltage on each cell is equal to half of the output voltage to prevent an overvoltage condition on either cell. If either cell fails as a short, the BAL pin does not prevent the second cell from being damaged.

NOTE

The LM3550 is not designed to work with low-voltage, single-cell super-capacitors.

8.2.2.1.2 Boost Capacitors

The LM3550 requires 4 external capacitors for proper operation ($C_1 = C_2 = 1 \mu F$; $C_{IN} = 4.7 \mu F$; $C_{OUT} = 2.2 \mu F$); TI recommends surface-mount multi-layer ceramic capacitors are recommended. These capacitors are small, inexpensive and have very low equivalent series resistance (ESR < 20 mΩ typical). Tantalum capacitors, OS-CON capacitors, and aluminum electrolytic capacitors are not recommended for use with the LM3550 due to their high ESR, as compared to ceramic capacitors.

For most applications, ceramic capacitors with X7R or X5R temperature characteristic are preferred for use with the LM3550. These capacitors have tight capacitance tolerance (as good as $\pm 10\%$) and hold their value over temperature (X7R: ±15% over −55°C to +125°C; X5R: ±15% over −55°C to +85°C).

Capacitors with Y5V or Z5U temperature characteristic are generally not recommended for use with the LM3550. Capacitors with these temperature characteristics typically have wide capacitance tolerance (+80%, −20%) and vary significantly over temperature (Y5V: 22%, −82% over −30°C to +85°C range; Z5U: 22%, −56% over 10°C to 85°C range). Under some conditions, a nominal 1µF Y5V or Z5U capacitor could have a capacitance of only 0.1 µF. Such detrimental deviation is likely to cause Y5V and Z5U capacitors to fail to meet the minimum capacitance requirements of the LM3550.

The recommended voltage rating for the capacitors is 10 V to account for DC bias capacitance losses.

8.2.2.1.3 Current Source FET

Choose the proper current source MOSFET to ensure accurate flash current delivery. N-channel MOSFETs (NFET) with allowed drain-to-source voltages (V_{DS}) greater than 5.5 V are required. In order to prevent damage to the current source NFET, special attention must be given to the pulsed-current rating of the MOSFET. The NFET must be sized appropriately to handle the desired flash current and flash duration. Most MOSFET manufacturers provide curves showing the pulsed performance of the NFET in the electrical characteristics section of their data sheets. The performance of the MOSFET rating at temperature, primarily temperatures greater than 40°C, must also be investigated to ensure NFET does not become thermally damaged during a flash pulse. An NFET possessing low R_{DSON} values helps improve the efficiency of the flash pulse.

[LM3550](http://www.ti.com/product/lm3550?qgpn=lm3550)

SNVS569C –MAY 2009–REVISED OCTOBER 2016 **www.ti.com**

8.2.2.1.4 ALD/TEMP Components

8.2.2.1.4.1 NTC Selection

NTC thermistors have a temperature-to-resistance relationship of:

 $R(T) = R_{25\degree}$ $\frac{\beta \left(\frac{1}{\Gamma^{2}C+273} - \frac{1}{298} \right)}{298}$

where

- β is given in the thermistor data sheet
- $R_{25^{\circ}C}$ is the thermistor's value at 25°C (11)

R1 in is chosen so that it is equal to:

$$
R1 = \frac{V_{TRIP}R_{T(TRIP)}}{(V_{BIAS} - V_{TRIP})}
$$

where

- $R_{T(TRIP)}$ is the thermistors value at the temperature trip point
- V_{BIAS} is shown in [Figure](#page-29-0) 50
- $V_{\text{TRIP}} = 800 \text{ mV (typical)}$ (12)

Choosing R1 here gives a more linear response around the temperature trip voltage. For example, with V_{BIAS} = 1.8 V, a thermistor whose nominal value at 25°C is 100 kΩ, and a β = 4500 K, the trip point is chosen to be 85°C. The value of R(T) at 85°C is:

$$
R(T) = 100 \text{ k}\Omega \times \text{e}^{\frac{p^6}{2(85 + 273)} \cdot \frac{1}{298}} = 7.959 \text{ k}\Omega
$$

R1 is then:
$$
\frac{0.8V \times 7.959 \text{ k}\Omega}{1.8V - 0.8V} = 6.367 \text{ k}\Omega
$$
 (13)

Setting the ALD/TEMP Sense High Register to $N = 50$ or hex 0x32 places the upper trip point to approximately 800 mV. Voltages higher than 800 mV prevent the flash LED from turning on. Based on [Figure](#page-29-0) 50, the Sense Low Register can be set to a lower code to give a second LED current threshold (70% flash). Voltages lower than the value stored in the Sense Low Register allow a full current flash.

Figure 50. Thermistor Resistive Divider Response vs Temperature

If the temperature changes during a flash event, meaning $V_{ALS/TEMP}$ crosses the sense high and/or sense low values, the current scales to the appropriate zone current.

Place the thermistor as close as possible to the flash LEDs. This provides the best thermal coupling (lowest thermal resistance).

Figure 51. Thermistor Voltage Divider and Sensing Circuit

8.2.2.1.4.2 Ambient Light Sensor

If the ALD/TEMP pin is not used for ambient/LED temperature monitoring, it can be used for ambient light detection. The LM3550 provides three regions of current control based upon ambient conditions. The three regions are defined using the Sense High and Sense Low Registers to set the zone boundaries (userconfigurable from 0 to 1 V). Most ambient light sensors are reverse-biased diodes that leak current proportional to the amount of ambient light reaching the sensor. This current is then translated into a voltage by using a resistor in series with the light sensor. The voltage-setting resistor varies based upon the desired ambient detection range and manufacturer.

Most ambient light sensors suggest placing a capacitor in parallel with the voltage-setting resistor in order to help filter the 50-, 60-Hz noise generated by fluorescent overhead lighting. This capacitor can range from no capacitor up to 10 µF. The key is to filter the noise so that the peak-to-peak voltage is less than 16 mV (LSB size of the ALD/TEMP sense high and sense low settings). Refer to the data sheet of the ambient light sensor for the recommended capacitor value.

The flash current drops to 70% of the peak once the voltage on the ALD/TEMP pin exceeds the sense low trip point.

Figure 52. Effect of ALD/TEMP Voltage Rising During a Flash

The flash event is not allowed to start if the voltage on ALD/TEMP is higher that the sense high trip point.

Figure 53. Effect of ALD/TEMP Voltage Dropping During a Flash

8.2.2.1.5 Thermal Protection

Internal thermal protection circuitry disables the LM3550 when the junction temperature exceeds 145°C (typical). This feature protects the device from being damaged by high die temperatures that might otherwise result from excessive power dissipation. The device recovers and operates normally when the junction temperature falls below 125°C (typical). It is important that the board layout provide good thermal conduction to keep the junction temperature within the specified operating ratings.

8.2.3 Application Curves

www.ti.com SNVS569C – MAY 2009–REVISED OCTOBER 2016

9 Power Supply Recommendations

The LM3550 is designed to operate from an input supply range of 2.7 V to 5.5 V. This input supply must be well regulated and provide the peak current required by the LED configuration.

10 Layout

10.1 Layout Guidelines

The UQFN is a leadless package with very good thermal properties. This package has an exposed DAP (die attach pad) at the underside center of the package measuring 1.86 mm \times 2.2 mm. The main advantage of this exposed DAP is to offer low thermal resistance when soldered to the thermal ground pad on the PCB. For good PCB layout TI recommends a 1:1 ratio between the package and the PCB thermal land. To further enhance thermal conductivity, the PCB thermal ground pad may include vias to a 2nd layer ground plane. For more detailed instructions on mounting UQFN packages, refer to *AN-1187 Leadless [Leadframe](http://www.ti.com/lit/pdf/SNOA401) Package (LLP)*.

The proceeding steps must be followed to ensure stable operation and proper current source regulation.

- 1. Bypass V_{IN} with at least a 4.7-µF ceramic capacitor. Connect the positive terminal of this capacitor as close as possible to V_{IN} .
- 2. Connect C_{OUT} as close as possible to the VOUT pin with at least a 2.2- μ F capacitor.
- 3. Connect the return terminals of the input capacitor and the output capacitor as close as possible to the exposed DAP and GND pins through low impedance traces.
- 4. Place the two 1-µF flying capacitors (C1 and C2) as close as possible to the LM3550 C1+, C1− and C2+, C2− pins.
- 5. To minimize losses during the flash pulse, TI recommends that the flash LEDs, the current source NFET, and current-setting resistor be placed as close as possible to the super capacitor.

10.2 Layout Example

11.5 Trademarks

E2E is a trademark of Texas Instruments. All other trademarks are the property of their respective owners.

11.6 Electrostatic Discharge Caution

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

11.7 Glossary

[SLYZ022](http://www.ti.com/lit/pdf/SLYZ022) — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

www.ti.com 10-Dec-2020

PACKAGING INFORMATION

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures. "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
