

Development Board EPC9047 Quick Start Guide

150 V Half-bridge with Gate Drive, Using EPC2033

Revision 3.0

DESCRIPTION

The EPC9047 development board is a 150 V maximum device voltage, 12 A maximum output current, half bridge with onboard gate drives, featuring the EPC2033 GaN field effect transistor (FET). The purpose of this development board is to simplify the evaluation process of the EPC2033 by including all the critical components on a single board that can be easily connected into the majority of existing converter topologies.

The EPC9047 development board measures 2" x 2" and contains two EPC2033 GaN FETs in a half bridge configuration with the On-Semi NCP51820 gate driver. The board also contains all critical components and the layout supports optimal switching performance. There are also various probe points to facilitate simple waveform measurement and efficiency calculation. A block diagram of the circuit is given in figure 1.

For more information on [EPC2033](#) please refer to the datasheet available from EPC at www.epc-co.com. The datasheet should be read in conjunction with this quick start guide.

Table 1: Performance Summary ($T_A = 25^\circ\text{C}$) EPC9047

| Symbol | Parameter | Conditions | Min | Nominal | Max | Units |
|-----------|--|-------------------------------------|-----|---------|-----|-------|
| V_{DD} | Gate Drive Input Supply Range | | 10 | 12 | 12 | V |
| V_{IN} | Bus Input Voltage Range ⁽¹⁾ | | | | 120 | V |
| I_{OUT} | Switch Node Output Current ⁽²⁾ | | | | 15 | A |
| V_{PWM} | PWM Logic Input Voltage Threshold ⁽³⁾ | Input 'High' | 3.5 | 5.5 | | V |
| | | Input 'Low' | 0 | 1.5 | | |
| | Minimum 'High' State Input Pulse Width | V_{PWM} rise and fall time < 10ns | 50 | | | ns |
| | Minimum 'Low' State Input Pulse Width ⁽⁴⁾ | V_{PWM} rise and fall time < 10ns | 200 | | | |

(1) Maximum input voltage depends on inductive loading, maximum switch node ringing must be kept under 150 V for EPC2033.

(2) Maximum current depends on die temperature – actual maximum current is affected by switching frequency, bus voltage and thermal cooling.

(3) When using the on board logic buffers, refer to the [NCP51820](#) datasheet when bypassing the logic buffers.

(4) Limited by time needed to 'refresh' high side bootstrap supply voltage.

QUICK START PROCEDURE

The EPC9047 development board is easy to set up as a buck or boost converter to evaluate the performance of two EPC2033 eGaN FETs. In addition to the deadtime features of the NCP51820 gate driver, this board includes a dead-time generating circuit that adds a delay from when the gate signal of one FET is commanded to turn off, to when the gate signal of the other FET is commanded to turn on. In the default configuration, the NCP51820 gate driver is set mode D (no-dead time, no-cross conduction protection - refer to datasheet for NCP51820) and the on-board dead time circuit provides the necessary dead time and ensures that both the high and low side FETs will not be turned on at the same time thus preventing a shoot through condition.

Single/dual PWM signal input settings

PWM1 and PWM2. Both input ports are used as inputs in dual-input mode where PWM1 connects to the upper FET and PWM2 connects to the lower FET. The PWM1 input port is used as the input in single-input mode where the circuit will generate the required complementary PWM with preset dead time for the FETs as shown in figure 2(a). This is the default configuration.

To select dual input mode, the zero-ohm resistor in position R5 needs to be removed and installed in position R6 as shown in figure 2(b).

Note: In dual mode there is no shoot-through protection as both gate signals can be set high at the same time. 2. The NCP51820 has an on-chip deadtime generator with several modes of operation. The EPC9047 disables the on-chip deadtime to maximize end user flexibility, but it makes the on-chip deadtime modes accessible through P1, R11, and R12. Refer to the NCP51820 datasheet for details on setting the dead time using P1, R11 and R12.

Buck converter configuration

To operate the board as a buck converter, either a single or dual PWM input can be chosen. Figure 3(a) shows the connection setup for single PWM input mode and figure 3(b) for the dual PWM input mode.

Note: It is important to provide the correct PWM signals that includes dead-time and polarity when operating in dual PWM input mode and not making use of the gate driver dead time function.

Once the input source and dead-time settings have been chosen and set, then the board can be operated.

1. With power off, connect the input power supply bus to VIN and ground/return to GND.
2. With power off, connect the switch node (SW) of the half bridge to your circuit as required (half bridge configuration). Or use the provided pads for inductor (L1) and output capacitors (Cout), as shown in figure 3.
3. With power off, connect the gate drive supply to VDD (J1, Pin-1) and ground return to GND (J1, Pin-2 indicated on the bottom side of the board).
4. With power off, connect the input PWM control signal to PWM1 and/or PWM2 according to the input mode setting chosen and ground return to any of GND J10 pins indicated on the bottom side of the board.
5. Turn on the gate drive supply – make sure the supply is at least 10 V but does not exceed 12 V.
6. Turn on the controller / PWM input source.
7. Making sure the initial input supply voltage is 0 V, turn on the power and slowly increase the voltage to the required value (**do not exceed the absolute maximum voltage**). Probe switching node to see switching operation.

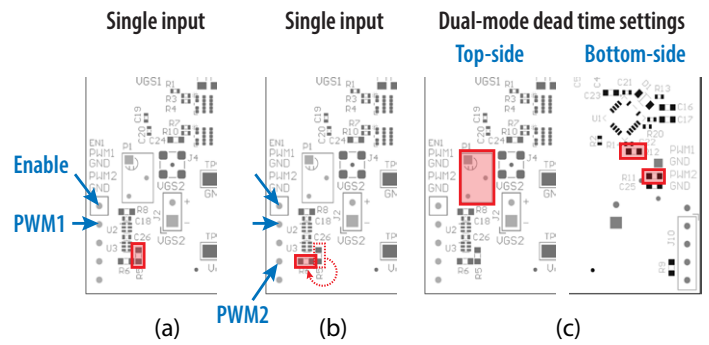

Figure 2: Input mode selection on J630

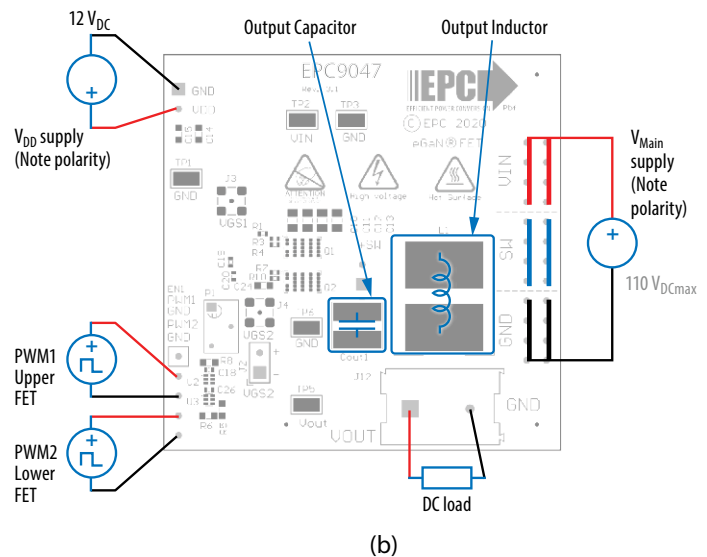

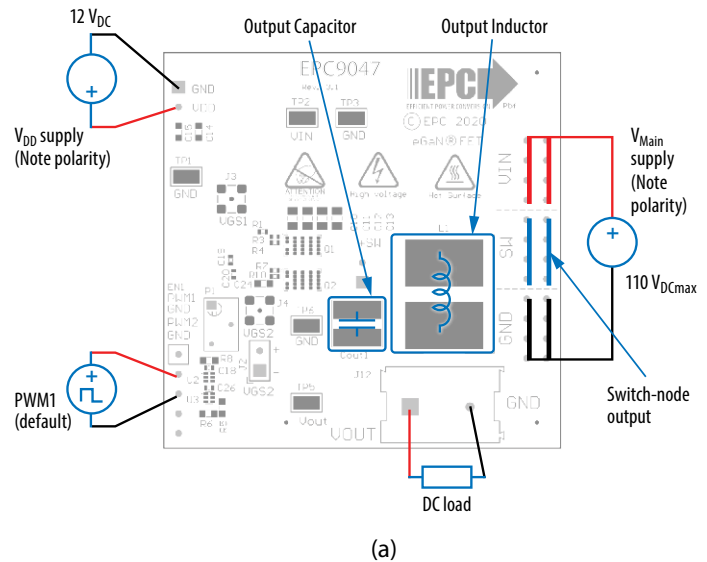

Figure 3: (a) Single-PWM input buck converter (b) Dual-PWM input buck converter configurations showing the supply, output capacitor, inductor, PWM, and load connections.

8. Once operational, adjust the PWM control, bus voltage, and load within the operating range and observe the output switching behavior, efficiency, and other parameters.
9. For shutdown, please follow steps in reverse.

Boost Converter configuration

Warning: Never operate the boost converter mode without a load as the output voltage can increase beyond the maximum ratings.

To operate the board as a boost converter, either a single or dual PWM input can be chosen. Figure 4(a) shows the connection setup for single PWM input mode and figure 4(b) for the dual PWM input mode.

Notes:

1. It is important to provide the correct PWM signals that includes dead-time and polarity when operating in dual PWM input mode and not making use of the gate driver dead time function.
2. Boost mode PWM converters are theoretically capable of generating arbitrarily high voltages, limited only by losses and component ratings. Review the operation of boost mode converters and make sure to avoid combinations of duty cycle and load that will generate higher voltages than the voltage rating of the development board and attached components.

Once the input source, dead-time settings and bypass configurations have been chosen and set then the boards can be operated.

1. The inductor (L1) and input capacitors (labeled as Cout) can either be soldered onto the board, as shown in figure 4, or provided off board.
2. With power off, connect the input power supply bus to V_{OUT} and ground / return to GND, or externally across the capacitor if the inductor L1 and Cout are provided externally. Connect the output voltage (labeled as VIN) to your circuit as required, e.g., resistive load.
3. With power off, connect the gate drive supply to V_{DD} (J1, Pin-1) and ground return to GND (J1, Pin-2 indicated on the bottom side of the board).
4. With power off, connect the input PWM control signal to PWM1 and/or PWM2 according to the input mode setting chosen and ground return to any of GND J10 pins indicated on the bottom side of the board.
5. Turn on the gate drive supply – make sure the supply is at least 10 V but does not exceed 12 V.
6. Turn on the controller / PWM input source.
7. **Making sure the output is not open circuit**, and the input supply voltage is initially 0 V, turn on the power and slowly increase the voltage to the required value (**do not exceed the absolute maximum voltage**). Probe switching node to see switching operation.
8. Once operational, adjust the PWM control, bus voltage, and load within the operating range and observe the output switching behavior, efficiency, and other parameters. Observe device temperature for operational limits.
9. For shutdown, please follow steps in reverse.

MEASUREMENT CONSIDERATIONS

Measurement connections are shown in figure 5. Figure 6 shows an actual switch-node voltage measurement when operating the board as a buck converter.

When measuring the switch node voltage containing high-frequency content, care must be taken to provide an accurate high-speed measurement. An optional two pin header (J5) and an MMCX connector (J6) are provided for switch-node measurement.

A differential probe is recommended for measuring the high-side bootstrap voltage. IsoVu probes from Tektronix has mating MMCX connector.

For regular passive voltage probes (e.g. TPP1000) measuring switch node using MMCX connector, probe adaptor is available. PN: 206-0663-xx.

NOTE. For information about measurement techniques, the EPC website offers: “AN023 Accurately Measuring High Speed GaN Transistors” and the How to GaN educational video series, including:HTG09-Measurement

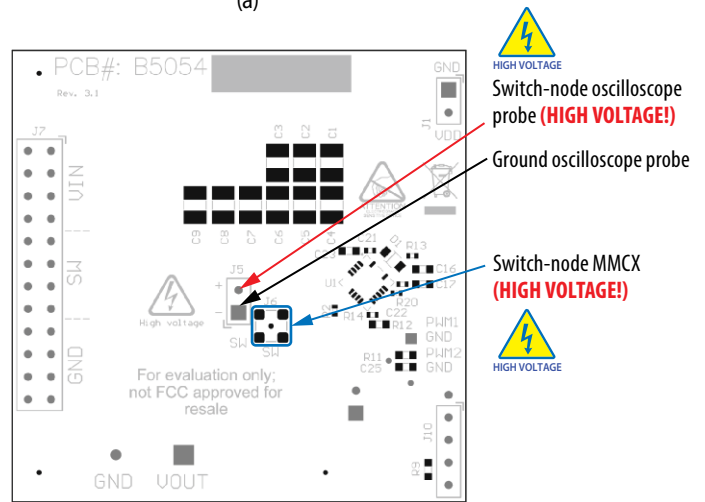

THERMAL CONSIDERATIONS

The EPC9047 is intended for bench evaluation with low ambient temperature and convection cooling. The addition of a heat-spreader or heatsink and forced air cooling can significantly increase the current rating of these devices, but care must be taken to not exceed the absolute maximum die temperature of 150°C.

NOTE. The EPC9047 development board does not have any current or thermal protection on board. For more information regarding the thermal performance of EPC eGaN FETs, please consult: D. Reusch and J. Glaser, *DC-DC Converter Handbook, a supplement to GaN Transistors for Efficient Power Conversion*, First Edition, Power Conversion Publications, 2015.

Demonstration Board Notification

The EPC9047 board is intended for product evaluation purposes only. It is not intended for commercial use nor is it FCC approved for resale. Replace components on the Evaluation Board only with those parts shown on the parts list (or Bill of Materials) in the Quick Start Guide. Contact an authorized EPC representative with any questions. This board is intended to be used by certified professionals, in a lab environment, following proper safety procedures. Use at your own risk.

As an evaluation tool, this board is not designed for compliance with the European Union directive on electromagnetic compatibility or any other such directives or regulations. As board builds are at times subject to product availability, it is possible that boards may contain components or assembly materials that are not RoHS compliant. Efficient Power Conversion Corporation (EPC) makes no guarantee that the purchased board is 100% RoHS compliant.

The Evaluation board (or kit) is for demonstration purposes only and neither the Board nor this Quick Start Guide constitute a sales contract or create any kind of warranty, whether express or implied, as to the applications or products involved.

Disclaimer: EPC reserves the right at any time, without notice, to make changes to any products described herein to improve reliability, function, or design. EPC does not assume any liability arising out of the application or use of any product or circuit described herein; neither does it convey any license under its patent rights, or other intellectual property whatsoever, nor the rights of others.
