Chapter 2

CPU and Memory Space

2. CPU and Memory Space

2.1 Overview

This LSI includes LAPIS Semiconductor's original 8-bit CPU nX-U8/100 and the memory model is "SMALL model" .
For details of the CPU nX-U8/100, see "nX-U8/100 Core Instruction Manual".

2.2 Program Memory Space

The program memory space is used to store program codes, table data (ROM window), or vector tables.
The program codes have a length of 16 bits and are specified by a 16-bit program counter (PC).
The ROM window area data has a length of 8 bits and can be used as table data.
The vector table, which has 16-bit long data, can be used as reset vectors, hardware interrupt vectors, and software interrupt vectors.
The program memory space consists of 1 segments and has 16-Kbyte (8-Kword) capacity.
Figure 2-1 shows the configuration of the program memory space.

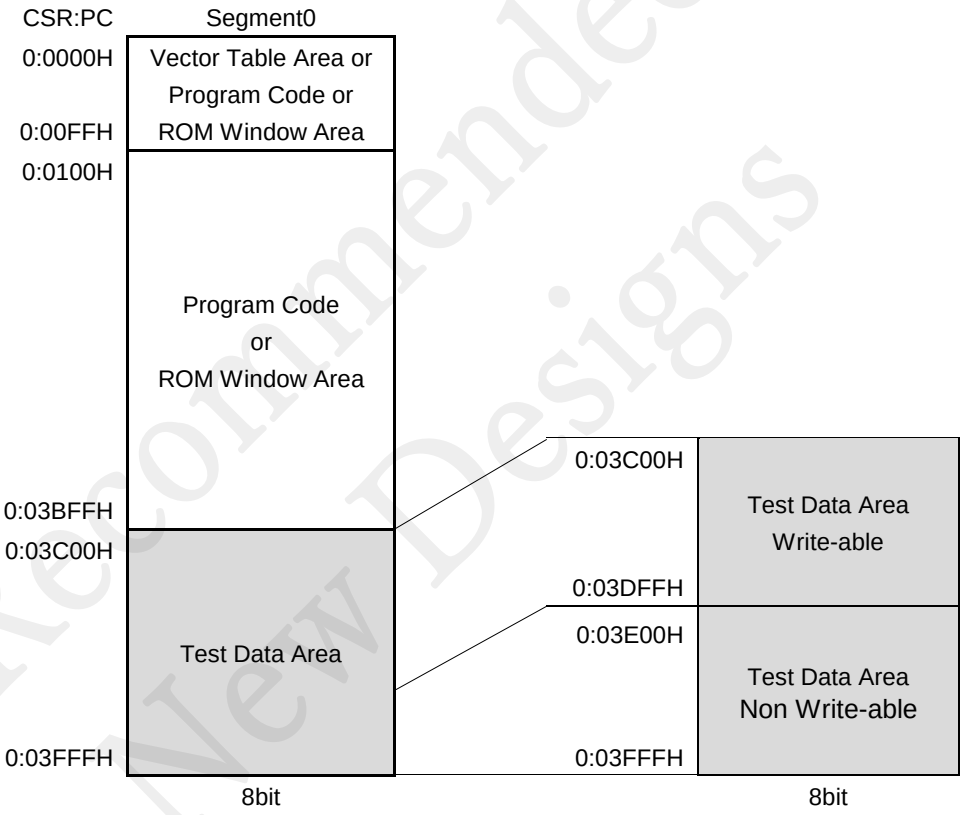

Figure 2-1 Configuration of Program Memory Space

Notes:
- Since test program data is stored in the 1024Byte (512Word) test data area (0:03C00H to 0:03FFFH) of Segment 0, this area cannot be used as a program code area.
- The address "0: 03C00H to 0: 03DFFH" in the test area is write-able and erase-able. Fill the area with "0FFH". If data in the area is uncertain or other data (i.e. not 0FFH), operating with the code can not be guranteed.
- Set "0FFH" data (BRK instruction) in the unused area of the program memory space.

2.3 Data Memory Space

The data memory space of this LSI consists of the ROM window area, 1KByte RAM area and SFR area of Segment 0 and the ROM reference areas of the Segment 1 and Segment 8.
The data memory stores 8-bit data and is specified by 20 bits consisting of higher 4 bits as DSR and lower 16 bits as addressing specified by each instruction.
Figure 2-2 shows the configuration of the data memory space.

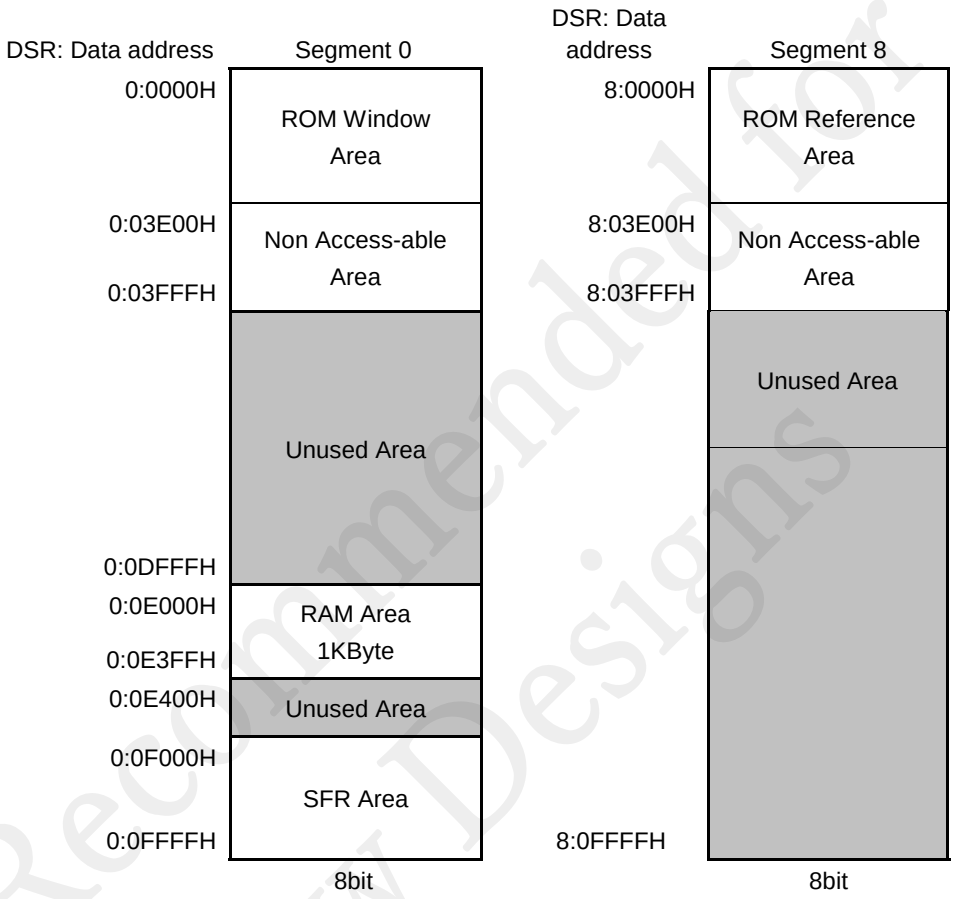

Figure 2-2 Configuration of Data Memory Space

Notes:
– The contents of the 1-Kbyte RAM area are undefined at system reset. Initialize this area by software.
– The contents of Segment 0 of the program memory space is read from the ROM reference area of Segment 8.

2.4 Instruction Length

The length of a instruction is 16 bits.

2.5 Data Type

The data types supported include byte (8 bits) and word (16 bits).

[Description of Bits]

- **POR** (bit 0)
  The POR bit is a flag that indicates that the power-on reset is generated. This bit is set to "1" when powered on.

POR	Description
0	Power-on reset not generated
1	Power-on reset generated

- **XSTR** (bit 1)
  The XSTR bit is a flag that indicates the generation of low-speed oscillation stop detect reset. When low-speed oscillation stops for the period specified by the low-speed oscillation stop detection time (TSTOP) or more, this bit is set to "1".

XSTR	Description
0	Low-speed oscillation stop detect reset not occurred
1	Low-speed oscillation stop detect reset occurred

- **WDTR** (bit 2)
  The WSDTR is a flag that indicates that the watchdog timer reset is generated. This bit is set to "1" when the reset by overflow of the watchdog timer is generated.

WDTR	Description
0	Watchdog timer reset not occurred
1	Watchdog timer reset occurred

Note:
No flag is provided that indicates the occurrence of reset by the RESET_N pin.

3.3 Description of Operation

3.3.1 Operation of System Reset Mode

System reset has the highest priority among all the processings and any other processing being executed up to then is cancelled.
The system reset mode is set by any of the following causes.

- Reset by the RESET_N pin
- Reset by power-on detection
- Reset by low-speed oscillation stop detection
- Reset by watchdog timer (WDT) overflow
- Software reset by the BRK instruction (only the CPU is reset)

In system reset mode, the following processing is performed.

(1) The power circuit is initialized, but not initialized by the reset by the BRK instruction execution. For the details of the power circuit, refer to Chapter 28, "Power Circuit".
(2) All the special function registers (SFRs) whose initial value is not undefined are initialized. However, the initialization is not performed by software reset due to execution of the BRK instruction. See Appendix A "Registers" for the initial values of the SFRs.
(3) CPU is initialized.
- All the registers in CPU are initialized.
- The contents of addresses 0000H and 0001H in the program memory are set to the stack pointer (SP).
- The contents of addresses 0002H and 0003H in the program memory are set to the program counter (PC). However, when the interrupt level (ELEEVL) of the program status word (PSW) at reset by the BRK instruction is 1 or lower, the contents of addresses 0004H and 0005H of the program memory are set in the program counter (PC). For the BRK instruction, see "nX-U8/100 Core Instruction Manual".

Note:
In system reset mode, the contents of data memory and those of any SFR whose initial value is undefined are not initialized and are undefined. Initialize them by software.
In system reset mode by the BRK instruction, no special function register (SFR) that has a fixed initial value is initialized either. Therefore initialize such an SFR by software.

MCU Control Function

4. MCU Control Function

4.1 Overview

The operating states of this LSI are classified into the following 4 modes including system reset mode:

System reset mode
Program run mode
HALT mode
STOP mode

For system reset mode, see Chapter 3, "Reset Function".

This LSI has a block control function, which power downs the circuits of unused peripherals (reset registers and stop clock supplies) to make even more reducing the current consumption.

4.1.1 Features

- HALT mode, where the CPU stops operating and only the peripheral circuit is operating
- STOP mode, where both low-speed oscillation and high-speed oscillation stop
- Stop code acceptor function, which controls transition to STOP mode
- Block control function, which power downs the circuits of unused peripherals (reset registers and stop clock supplies).

4.1.2 Configuration

Figure 4-1 shows an operating state transition diagram.

4.2 Description of Registers

4.2.1 List of Registers

Address	Name	Symbol (Byte)	Symbol (Word)	R/W	Size	Initial value
0F008H	Stop code acceptor	STPACP	—	W	8	—
0F009H	Standby control register	SBYCON	—	W	8	00H
0F028H	Block control register 0	BLKCON0	—	R/W	8	00H
0F029H	Block control register 1	BLKCON1	—	R/W	8	00H
0F02AH	Block control register 2	BLKCON2	—	R/W	8	00H
0F02BH	Block control register 3	BLKCON3	—	R/W	8	00H
0F02CH	Block control register 4	BLKCON4	—	R/W	8	00H

4.2.2 Stop Code Acceptor (STPACP)

Address: 0F008H
Access: W
Access size: 8 bits
Initial value: — (Undefined)

	7	6	5	4	3	2	1	0
STPACP	—	—	—	—	—	—	—	—
W	W	W	W	W	W	W	W	W
Initial value	—	—	—	—	—	—	—	—

STPACP is a write-only special function register (SFR) that is used for setting a STOP mode.
When STPACP is read, "00H" is read.
When data is written to STPACP in the order of "5nH"(n: an arbitrary value) and "0AnH"(n: an arbitrary value), the stop code acceptor is enabled. When the STP bit of the standby control register (SBYCON) is set to "1" in this state, the mode is changed to the STOP mode. When the STOP mode is set, the STOP code acceptor is disabled.
When another instruction is executed between the instruction that writes "5nH" to STPACP and the instruction that writes "0AnH", the stop code acceptor is enabled after "0AnH" is written. However, if data other than "0AnH" is written to STPACP after "5nH" is written, the "5nH" write processing becomes invalid so that data must be written again starting from "5nH".
During a system reset, the stop code acceptor is disabled.

Note:
The STOP code acceptor can not be enabled on the condition of that both any interrupt enable flag and the corresponding interrupt request flag are "1"(An interrupt request occurrence with resetting MIE flag will have the condition).

4.2.3 Standby Control Register (SBYCON)

Address: 0F009H
Access: W
Access size: 8 bits
Initial value: 00H

	7	6	5	4	3	2	1	0
SBYCON	—	—	—	—	—	—	STP	HLT
W	W	W	W	W	W	W	W	W
Initial value	0	0	0	0	0	0	0	0

SBYCON is a special function register (SFR) to control operating mode of MCU.

[Description of Bits]

- **STP** (bit 1)
  The STP bit is used for setting the STOP mode. When the STP bit is set to "1" with the stop code adapter enabled by using STPACP, the mode is changed to the STOP mode. When the NMI interrupt request or the P00–P03 interrupt request enabled by the interrupt enable register 1 (IE1) is issued, the STP bit is set to "0" and the LSI returns to the program run mode.

- **HLT** (bit 0)
  The HALT bit is used for setting a HALT mode. When the HALT bit is set to "1", the mode is changed to the HALT mode. When the NMI interrupt request, WDT interrupt request, or enabled (the interrupt enable flag is "1") interrupt request is issued, the HALT bit is set to "1" and the mode is returned to program run mode.

STP	HLT	Description
0	0	Program run mode (initial value)
0	1	HALT mode
1	0	STOP mode
1	1	Prohibited

Note:
The mode can not be changed to HALT mode or STOP mode on the condition of that both any interrupt enable flag and the corresponding interrupt request flag are "1"(An interrupt request occurrence with resetting MIE flag will have the condition).
When a maskable interrupt source (interrupt with enable bit) occurs while the MIE flag of the program status word (PSW) in the nX-U8/100 core is "0", the STOP mode and the HALT mode are simply released and interrupt processing is not performed. Refer to the "nX-U8/100 Core Instruction Manual" for details of PSW.

4.3 Description of Operation

4.3.1 Program Run Mode

The program run mode is the state where the CPU executes instructions sequentially.
At power-on reset, RESET_N pin reset, low-speed oscillation stop detect reset, or WDT overflow reset, the CPU executes instructions from the addresses that are set in addresses 0002H and 0003H of program memory (ROM) after the system reset mode is released.
At reset by the BRK instruction, the CPU executes instructions from the addresses that are set in the addresses 0004H and 0005H of the program memory after the system reset mode is released. However, when the value of the interrupt level bit (ELEVEL) of the program status word (PSW) is 02H or higher at execution of the BRK instruction (after the occurrence of the WDT interrupt or NMI interrupt), the CPU executes instructions from the addresses that are set in the addresses 0002H and 0003H.
For details of the BRK instruction and PSW, see the "nX-U8/100 Core Instruction Manual" and for the reset function, see Chapter 3, "Reset Function".

4.3.2 HALT Mode

The HALT mode is the state where the CPU interrupts execution of instructions and only the peripheral circuits are running.
When the HLT bit of the standby control register (SBYCON) is set to "1", the HALT mode is set.
When a NMI interrupt request, a WDT interrupt request, or an interrupt request enabled by an interrupt enable register (IE1–IE7) is issued, the HLT bit is set to "0" on the falling edge of the next system clock (SYSCLK) and the HALT mode is returned to the program run mode released.
Figure 4-2 shows the operation waveforms in HALT mode.

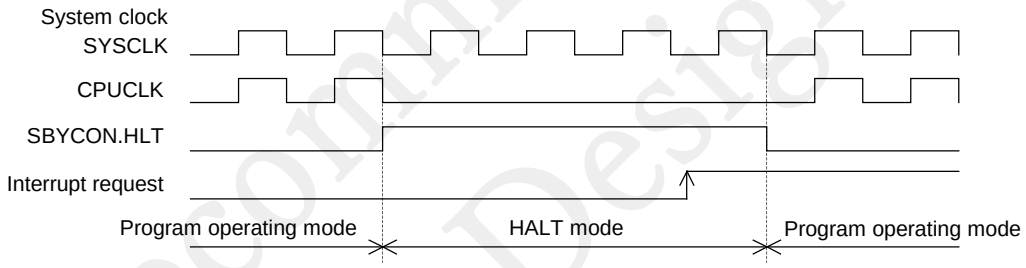

Figure 4-2 Operation Waveforms in HALT Mode

Note:
Since up to two instructions are executed during the period between HALT mode release and a transition to interrupt processing, place two NOP instructions next to the instruction that sets the HLT bit to "1".

4.3.3 STOP Mode

The STOP mode is the state where low-speed oscillation and high-speed oscillation stop and the CPU and peripheral circuits stop the operation.
When the stop code acceptor is enabled by writing "5nH"(n: an arbitrary value) and "0AnH"(n: an arbitrary value) to the stop code acceptor (STPACP) sequentially and the STP bit of the standby control register (SBYCON) is set to "1", the STOP mode is entered. When the STOP mode is set, the stop code acceptor is disabled.
When a NMI interrupt request or an interrupt-enabled (the interrupt enable flag is "1") P00 to P003 interrupt request is issued, the STP bit is set to "0", the STOP mode is released, and the mode is returned to the program run mode.

4.3.3.1 STOP Mode When CPU Operates with Low-Speed Clock

When the stop code acceptor is in the enabled state and the STP bit of SBYCON is set to "1", the STOP mode is entered, stopping low-speed oscillation and high-speed oscillation.
When the NMI interrupt request or the interrupt-enabled (the interrupt enable flag is "1") P00 to P03 interrupt request is issued, the STP bit is set to "0" and low-speed oscillation restarts. If the high-speed clock was oscillating before the STOP mode is entered, the high-speed oscillation restarts. When the high-speed clock was not oscillating before the STOP mode is entered, high-speed oscillation does not start.
When an interrupt request occurs, the STOP mode is released after the elapse of the low-speed oscillation start time (TXTL) and the low-speed clock (LSCLK) oscillation settling time (8192-pulse count), the mode is returned to the program mode, and the low-speed clock (LSCLK) restarts supply to the peripheral circuits. If the high-speed clock already started oscillation at this time, the high-speed clocks (OSCLK and HSCLK) also restart supply to the peripheral circuits.
For the low-speed oscillation start time (TXTL), see the "Electrical Characteristics" Section in Appendix C.
Figure 4-3 shows the operation waveforms in STOP mode when CPU operates with the low-speed clock.

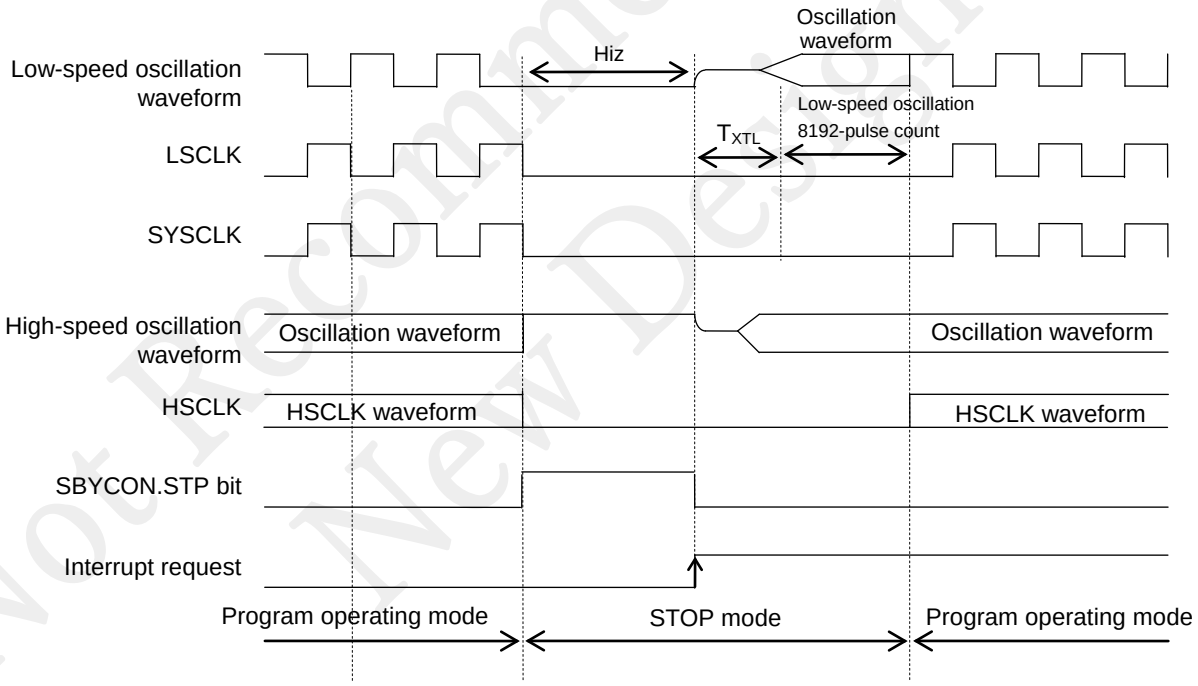

Figure 4-3 Operation Waveforms in STOP Mode When CPU Operates with Low-Speed Clock

4.3.3.2 STOP Mode When CPU Operates with High-Speed Clock

When the CPU is operating with a high-speed clock and the STP bit of SBYCON is set to "1" with the stop code acceptor enabled, the STOP mode is entered and high-speed oscillation and low-speed oscillation stop.
When the NMI interrupt request or the interrupt-enabled (the interrupt enable flag is "1") P00 to P03 interrupt request is issued, the STP bit is set to "0" and the low-speed and high-speed oscillation restart.
When an interrupt request is issued, the STOP mode is released after the elapse of the high-speed oscillation start time (T_{RC}) and the high-speed clock (OSCLK) oscillation stabilization time (8192-pulse count), the mode is returned to the program run mode, and the high-speed clocks (OSCLK and HSCLK) restart supply to the peripheral circuits.
The low-speed clock (LSCLK) restarts supply to the peripheral circuits after the elapse of the low-speed oscillation start time (T_{XTL}) and low-speed clock (LSCLK) oscillation settling time (8192 count).
For the high-speed oscillation start time (T_{RC}) and low-speed oscillation start time (T_{XTL}), see the "Electrical Characteristics" Section in Appendix C.
Figure 4-4 shows the operation waveforms in STOP mode when CPU operates with the high-speed clock.

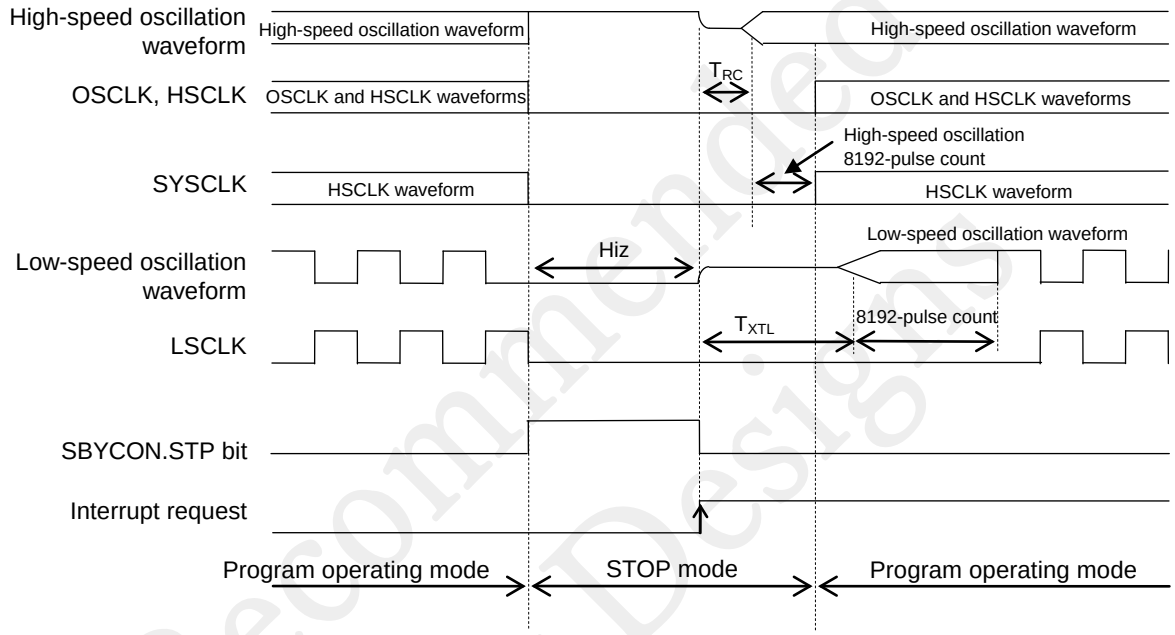

Figure 4-4 Operation Waveforms in STOP Mode When CPU Operates with High-Speed Clock

Note:
The STOP mode is entered two cycles after the instruction that sets the STP bit to "1" and up to two instructions are executed during the period between STOP mode release and a transition to interrupt processing. Therefore, place two NOP instructions next to the instruction that set the STP bit to "1".

4.3.3.3 Note on Return Operation from STOP/HALT Mode

The operation of returning from the STOP mode and HALT mode varies according to the interrupt level (ELEVEL) of the program status word (PSW), master interrupt enable flag (MIE), the contents of the interrupt enable register (IE0 to IE3), and whether the interrupt is a non-maskable interrupt or a maskable interrupt.
For details of PSW and the IE and IRQ registers, see "nX-U8/100 Core Instruction Manual" and Chapter 5, "Interrupt", respectively.

Table 4-1 and Table 4-2 show the return operations from STOP/HALT mode.

Table 4-1 Return Operation from STOP/HALT Mode (Non-Maskable Interrupt)

ELEVEL	MIE	IEn.m	IRQn.m	Return operation from STOP/HALT mode
*	*	–	0	Not returned from STOP/HALT mode.
3	*	–	1	After the mode is returned from STOP/HALT mode, the program operation restarts from the instruction following the instruction that sets the STP/HLT bit to "1". The program operation does not go to the interrupt routine.
0, 1, 2	*	–	1	After the mode is returned from the STOP/HALT mode, program operation restarts from the instruction following the instruction that sets the STP/HLT bit to "1", then goes to the interrupt routine.

Table 4-2 Return Operation from STOP/HALT Mode (Maskable Interrupt)

ELEVEL	MIE	IEn.m	IRQn.m	Return operation from STOP/HALT mode
*	*	*	0	Not returned from STOP/HALT mode.
*	*	0	1	
*	0	1	1	After the mode is returned from STOP/HALT mode, the program operation restarts from the instruction following the instruction that sets the STP/HLT bit to "1". The program operation does not go to the interrupt routine.
2,3	1	1	1	
0, 1	1	1	1	After the mode is returned from the STOP/HALT mode, program operation restarts from the instruction following the instruction that sets the STP/HLT bit to "1", then goes to the interrupt routine.

Notes:
- If the ELEVEL bit is 0H, it indicates that the CPU is performing neither nonmaskable interrupt processing nor maskable interrupt processing nor software interrupt processing.
- If the ELEVEL bit is 1H, it indicates that the CPU is performing maskable interrupt processing or software interrupt processing. (ELEVEL is set during interrupt transition cycle.)
- If the ELEVEL bit is 2H, it indicates that the CPU is performing non-maskable interrupt processing. (ELEVEL is set during interrupt transition cycle.)
- If the ELEVEL bit is 3H, it indicates that the CPU is performing interrupt processing specific to the emulator. This setting is not allowed in normal applications.

4.3.4 Block Control Function

This LSI has a block control function, which resets and completely turns operating circuits of unused peripherals off to make even more reducing current consumption.

When certain bits of block control registers are set to "1", corresponding peripherals are reset (all registers are reset) and operating clocks for the peripherals stop. Writing to every SFR (special function register) in the corresponding peripherals is not valid while the bits of block control registers are set to "1" and returns the initial value for read. Ensure the bits are reset to "0" before using the peripherals to enable the operation.

BLKCON0 register controls(disables/enables) operation of Timer 0, Timer 1, Timer 2 and Timer 3.
BLKCON1 register controls(disables/enables) operation of Capture, 1kHz Timer and PWM.
BLKCON2 register controls(disables/enables) operation of I2C, UART and SSIO.
BLKCON3 register controls(disables/enables) operation of Melody/Buzzer.
BLKCON4 register controls(disables/enables) operation of LCD driver, Battery Level Detector, 32kHz oscillation stop detector, RC type A/D converter and SAR type A/D converter.

Note:
DXTSP bit (bit 4) of BLKCON4 register disables the operation of 32kHz oscillation stop detector in HALT mode only. See the each chapter for detail about the opeation of each peripheral and relevant notes.

* ML610Q411PA has a different specification of that the circuits related to 32kHz oscillation stop detect are reset and turned off (disabled) when the DXTSP bit is set to "1" regardless the CPU in HALT mode or not.

5.3 Description of Operation

With the exception of the watchdog timer interrupt (WDTINT) and the NMI interrupt (NMINT), interrupt enable/disable for 19 sources is controlled by the master interrupt enable flag (MIE) and the individual interrupt enable registers (IE1 to 7). WDTINT and NMIINT are non-maskable interrupts.
When the interrupt conditions are satisfied, the CPU calls a branching destination address from the vector table determined for each interrupt source and the interrupt shift cycle starts to branch to the interrupt processing routine.
Table 5-1 lists the interrupt sources.

- Please define vector tables for all unused interrupts for fail safe.

5.3.1 Maskable Interrupt Processing

When an interrupt is generated with the MIE flag set to "1", the following processing is executed by hardware and the processing of program shifts to the interrupt destination.

(2) Transfer CSR to ECSR1.
(3) Transfer PSW toEPSW1.
(4) Set the MIE flag to "0".
(5) Set the ELEVEL field to"1".
(6) Load the interrupt start address into PC.

5.3.2 Non-Maskable Interrupt Processing

When an interrupt is generated regardless of the state of MIE flag, the following processing is performed by hardware and the processing of program shifts to the interrupt destination.

(1) Transfer PC to ELR2.
(2) Transfer CSR to ECSR2.
(3) Transfer PSW to EPSW2.
(4) Set the ELEVEL field to "2".
(5) Load the interrupt start address into PC.

5.3.3 Software Interrupt Processing

A software interrupt is generated as required within an application program. When the SWI instruction is performed within the program, a software interrupt is generated, the following processing is performed by hardware, and the processing program shifts to the interrupt destination. The vector table is specified by the SWI instruction.

(1) Transfer PC to ELR1.
(2) Transfer CSR to ECSR1.
(3) Transfer PSW to EPSW1.
(4) Set the MIE flag to "0".
(5) Set the ELEVEL field to "1".
(6) Load the interrupt start address into PC.

5.3.5 Interrupt Disable State

Even if the interrupt conditions are satisfied, an interrupt may not be accepted depending on the operating state. This is called an interrupt disabled state. See below for the interrupt disabled state and the handling of interrupts in this state.

Interrupt disabled state 1: Between the interrupt shift cycle and the instruction at the beginning of the interrupt routine
When the interrupt conditions are satisfied in this section, an interrupt is generated immediately following the execution of the instruction at the beginning of the interrupt routine corresponding to the interrupt that has already been enabled.

Interrupt disabled state 2: Between the DSR prefix instruction and the next instruction
When the interrupt conditions are satisfied in this section, an interrupt is generated immediately after execution of the instruction following the DSR prefix instruction.

Reference:
For the DSR prefix instruction, see "nX-U8/100 Core Instruction Manual".

6.1 Overview

The clock generation circuit generates and provides a low-speed clock (LSCLK), 2× low-speed clock (LSCLK2), a high-speed clock (HSCLK), a system clock (SYSCLK), and a high-speed output clock (OUTCLK). LSCLK, LSCLK×2, and HSCLK are time base clocks for the peripheral circuits, SYSCLK is a basic operation clock of CPU, and OUTCLK is a clock that is output from a port.
For the OUTCLK output port, see Chapter 19, "Port 2". Additionally, for the STOP mode described in this chapter, see Chapter 4, "MCU Control Function", and for BLD, see Chapter 27, "Battery Level Detection Circuit".

- Low-speed clock: 32.768 kHz crystal oscillation mode
  – 32.768kHz Crystal oscillation mode
  – Capable of generating LSCLK × 2 (64 kHz) to be used for some peripherals.
- High-speed clock: Software selection
  – 500 kHz RC oscillation mode

6.1.2 Configuration

Figure 6-1 shows the configuration of the clock generation circuit.

Note:
This LSI starts operation with a clock generated by dividing the 500 kHz RC oscillation frequency by 8 after power-on or a system reset. At initialization by software, set the FCON0 or FCON1 register to switch the clock to a required one. This LSI is not guaranteed under a condition where a low-speed clock is not supplied.

[Description of Bits]

- **SYSC1, SYSC0** (bits 1, 0)

The SYSC1 and SYSC0 bits are used to select the frequency of the high-speed clock (HSCLK) used for system clock and periphera1 circuits (including high-speed time base counter). OSCLK, 1/2OSCLK, 1/4OSCLK, or 1/8OSCLK can be selected. The maximum operating frequency guaranteed for the system clock (SYSCLK) of this LSI is 500kHz. At system reset, 1/8OSCLK is selected.

0	0	OSCLK
0	1	1/2OSCLK
1	0	1/4OSCLK
1	1	1/8OSCLK (initial value)

- **OSCM0** (bits 2)

The OSCM0 bit is used to select the mode of the high-speed clock generation circuit. RC oscillation mode or external clock input mode can be selected.
The setting of OSCM0 can be changed only when high-speed oscillation is being stopped (ENOSC bit of FCON1 is "0"). At system reset, RC oscillation mode is selected.

Note:
- To switch the mode of the high-speed clock generation circuit using the OSCM0 bit, stop the high-speed oscillation and set the system clock to the low-speed clock (set the ENOSC bit and SYSCLK of FCON1 to "0").
- The maximum operating frequency guaranteed for the system clock (SYSCLK) of this LSI is 500kHz. The external clock that is connected to the P10/OSC0 pins must not exceed 500kHz. For more detail about the specification, see Appendix C, "Electrical Characteristics"

FCON1 is a special function register (SFR) to control the high-speed clock generation circuit and to select system clock.

[Description of Bits]

- **SYSCLK** (bit 0)
  The SYSCLK bit is used to select system clock. It allows selection of the low-speed clock (LSCLK) or HSCLK (1/nOSCLK: n = 1, 2, 4, 8) selected by using the high-speed clock frequency select bit (SYSC1, 0) of FCON0.
  When the oscillation of high-speed clock is stopped (ENOSC bit = "0"), the SYSCLK bit is fixed to "0" and the low-speed clock (LSCLK) is selected for system clock.

SYSCLK	Description
0	LSCLK
1	HSCLK (initial value)

- **ENOSC** (bit 1)
  The ENOSC bit is used to select enable/disable of the oscillation of the high-speed clock oscillator.

ENOSC	Description
0	Disables high-speed oscillation
1	Enables high-speed oscillation (initial value)

- **ENMLT** (bit 2)
  The ENMLT bit is used to select enable/disable of the operation of the 2× low-speed clock (LSCLK×2).

ENMLT	Description

1	Enables 2× low-speed clock operation

6.3 Description of Operation

6.3.1 Low-Speed Clock

6.3.1.1 Low-Speed Clock Generation Circuit

Figure 6-2 shows the configuration of the low-speed clock generation circuit.

A low-speed clock generation circuit is provided with an external 32.768 kHz crystal. To match the oscillation frequency by using a trimmer capacitor, connect external capacitors (C_{GL} and C_{DL}) as required.
In STOP mode, V_{DDX} is powered off to stop low-speed oscillation, and the XT0 and XT1 pins become Hiz (Hi Impedance state). When the ENMLT bit of FCON1 is set to "1", the 2× low-speed clock circuit starts to generalte the LSCLK×2(64kHz).

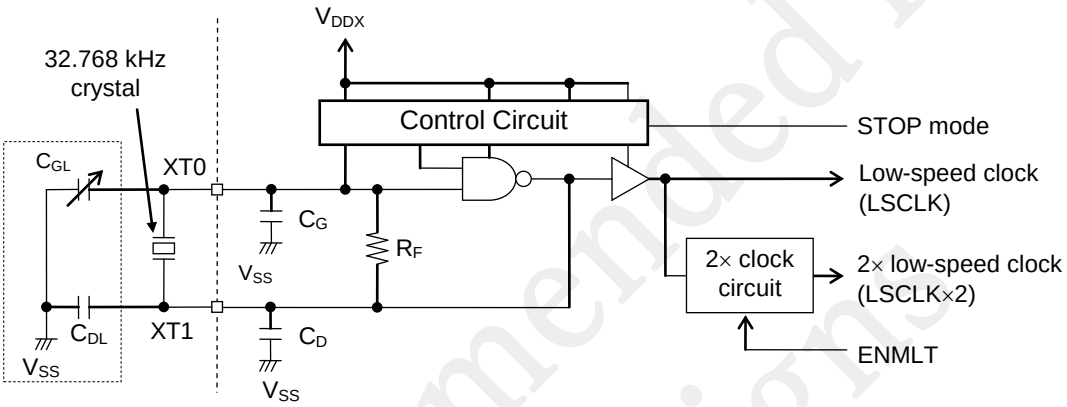

Figure 6-2 Circuit Configuration of 32.768 kHz Crystal Oscillation Mode

Notes:
- Install a crystal as close to the LSI as possible and make sure that signals causing noise and power supply wiring are not near the crystal and its wiring.
- Note that oscillation may stop due to condensation.
- The internal loading capacitance CG=CD=12pF (Typ.) exist in the low-speed clock generation circuit. This value does not include parasitic bond and package capacitance.

6.3.1.2 Operation of Low-Speed Clock Generation Circuit

The low-speed clock generation circuit is activated by the occurrence of power ON reset.
A low-speed clock (LSCLK) is supplied to the peripheral circuits after the elapse of the low-speed oscillation start period (T_{XTL}) and oscillation stabilization period (8192 counts) after powered on.
The low-speed clock generation stops the oscillation in STOP mode. When the oscillation is resumed by releasing of the STOP mode by external interrupt, LSCLK is supplied to the peripheral circuits after the elapse of the low-speed oscillation start period (T_{XTL}) and low-speed clock (LSCLK) oscillation stabilization period. For STOP mode, see Chapter 4, "MCU Control Function".
Figure 6-3-1 shows the waveforms of the low-speed clock generation circuit. For the low-speed oscillation start time (T_{XTL}), see Appendix C, "Electrical Characteristics".

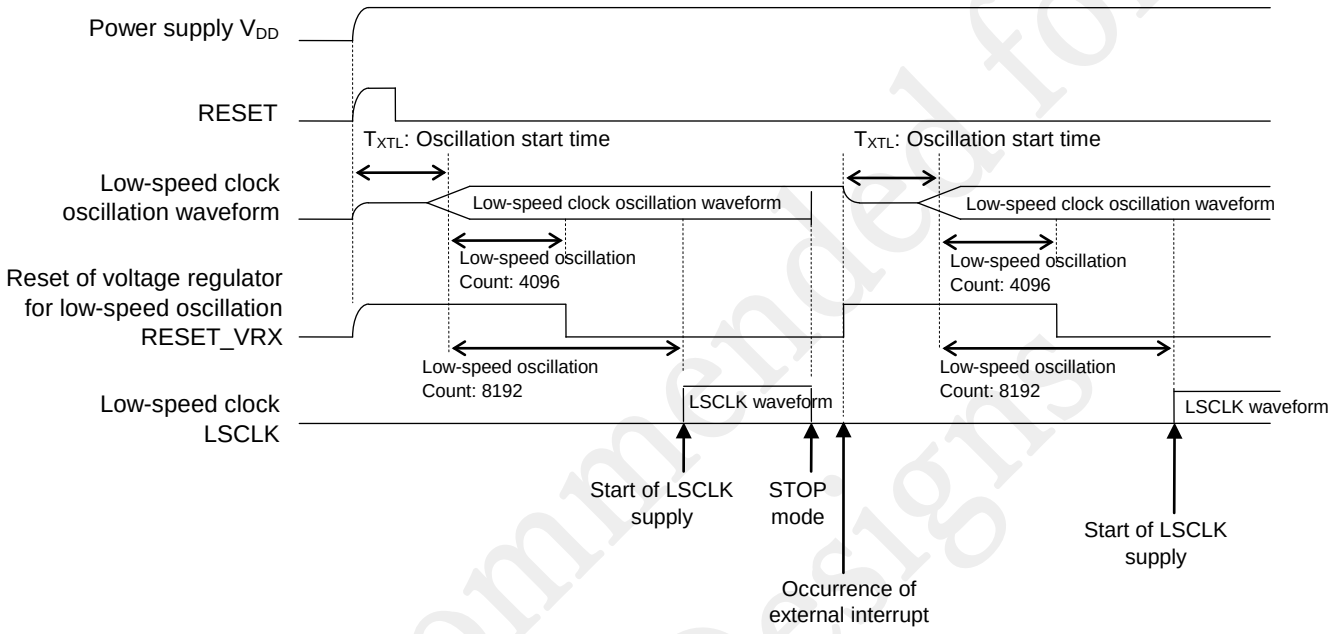

Figure 6-3-1 Operation of Low-Speed Clock Generation Circuit

Note:
After the power supply is turned on, CPU starts operation with a high-speed clock (500 kHz RC oscillation). It is recommended to switch to the low-speed clock after confirming that the low-speed clock is oscillating by checking that the 128 Hz interrupt request bit (Q128H) of the low-speed time base counter is "1". If the clock is switched before the low-speed clock oscillates, the CPU stops operation until oscillation of the low-speed clock starts.

6.3.2 High-Speed Clock

Setting of the OSCM0 bits of the frequency control register 0 (FCON0) allows selection of the 500 kHz RC oscillation mode or external clock input mode for the high-speed clock generation circuit.

6.3.2.1 500 kHz RC Oscillation

In RC oscillation mode (OSCM0 = "0"), supply of OSCLK (high-speed oscillation clock) is started when RC oscillation clock pulse count reaches 128 after oscillation is enabled (ENOSC is set to "1").
In 500 kHz RC oscillation mode, both the P10/OSC0 pin can be used as general-purpose input ports.
Figure 6-4 shows the circuit configuration in RC oscillation mode.

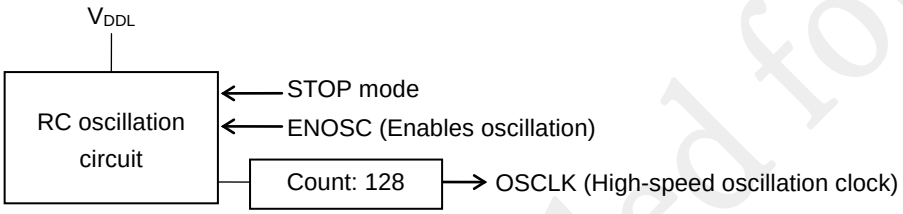

Figure 6-4 Circuit Configuration in RC Oscillation Mode

Notes:
- The RC oscillation mode is allowed within the range of V_{DD} = 1.3 V to 3.6 V.
- After system reset mode is released, supply of OSCLK starts after the RC oscillation clock pulse count reaches 8192. After release of a STOP mode, supply of OSCLK starts.

6.3.2.2 External Clock Input Mode

In external clock input mode, external clock is input from the P10/OSC0 pin.
Figure 6-5 shows the circuit configuration in external clock input mode.

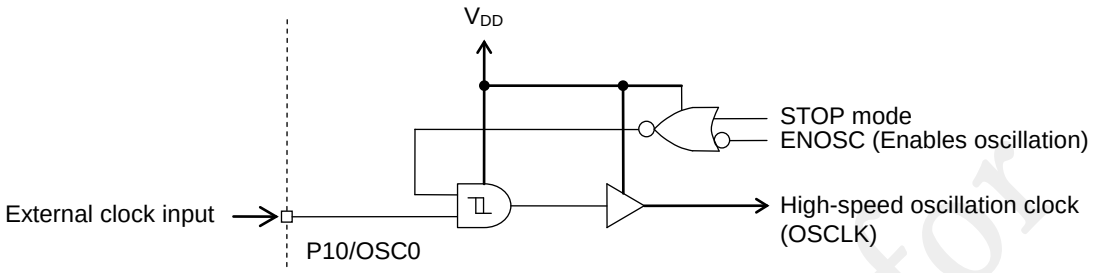

Figure 6-5 Circuit Configuration in External Clock Input Mode

Notes:
- The external clock input mode can be used within a V_{DD} range of 1.8 V to 3.6 V. Select a frequency according to the operation voltage range by using the power supply voltage detection circuit (BLD).
- Since the diodes are included between the P10/OSC0 pin and V_{DD} and between the P10/OSC0 pin and V_{SS}, do not apply voltages higher than V_{DD} and lower than V_{SS} to the P10/OSC0 pin.
- If the P10/OSC0 pin is left open in external clock input mode, excessive current can flow. Therefore, make sure that the "H" level (V_{DD}) or the "L" level (V_{SS}) is input.
- The maximum operating frequency guaranteed for the system clock (SYSCLK) of this LSI is 500kHz. The external clock that is connected to the P10/OSC0 pins must not exceed 500kHz. For more detail about the specification, see Appendix C, "Electrical Characteristics"

6.3.2.3 Operation of High-Speed Clock Generation Circuit

The high-speed clock generation circuit is activated in 500Hz RC oscillation mode by power-on reset generation.
As a result of the occurrence of power-on reset, the circuit goes into system reset mode and then shifts to program operating mode after the elapse of the high-speed RC oscillation start time (T_{RC}) and the oscillation stabilization time (Count: 8192) of the high-speed oscillation clock (OSCLK) and at the same time, a high-speed clock (HSCLK) is supplied to the peripheral circuits.
Figure 6-6 shows the waveforms of the high-speed clock generation circuit at power on. For the high-speed RC oscillation start time (T_{RC}), see Appendix C, "Electrical Characteristics".

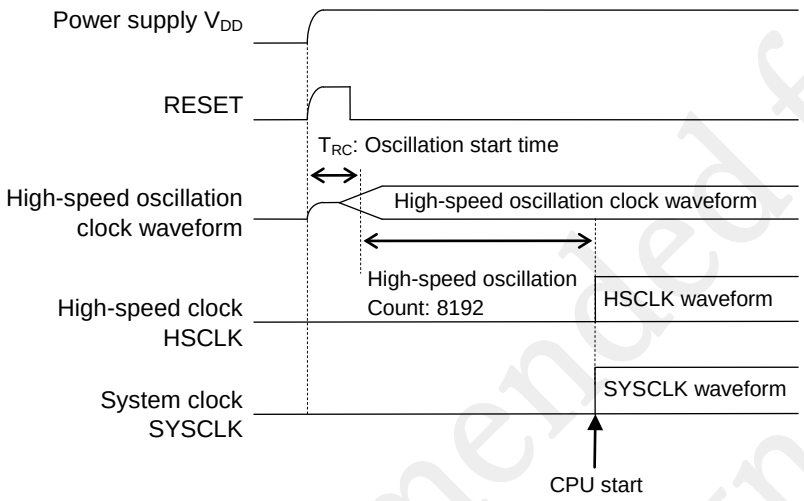

Figure 6-6 Operation of High-Speed Clock Generation Circuit at Power-On

The high-speed clock generation circuit allows selection of an oscillation mode and start/stop of oscillation by using the frequency control registers 0 and 1 (FCON0 and FCON1).
Oscillation can be started by setting the ENOSC bit to "1" after selecting a high-speed oscillation mode in FCON0 and a high-speed oscillation frequency. After the start of oscillation, HSCLK starts supply of a clock to the peripheral circuits following the elapse of the high-speed oscillation start period (T_{RC}) and the oscillation stabilization period of the high-speed oscillation clock.
The high-speed clock generation circuit stops oscillation in STOP mode. When the STOP mode is released by external interrupt, HSCLK supplies clocks to peripheral circuits following the elapse of the high-speed oscillation start period (T_{RC}) and the oscillation stabilization period of the high-speed clock. The oscillation stabilization period is the duration of 128 clock pulses.

Figure 6-7 shows the waveforms of the high-speed clock generation circuit in crystal/ceramic oscillation mode.

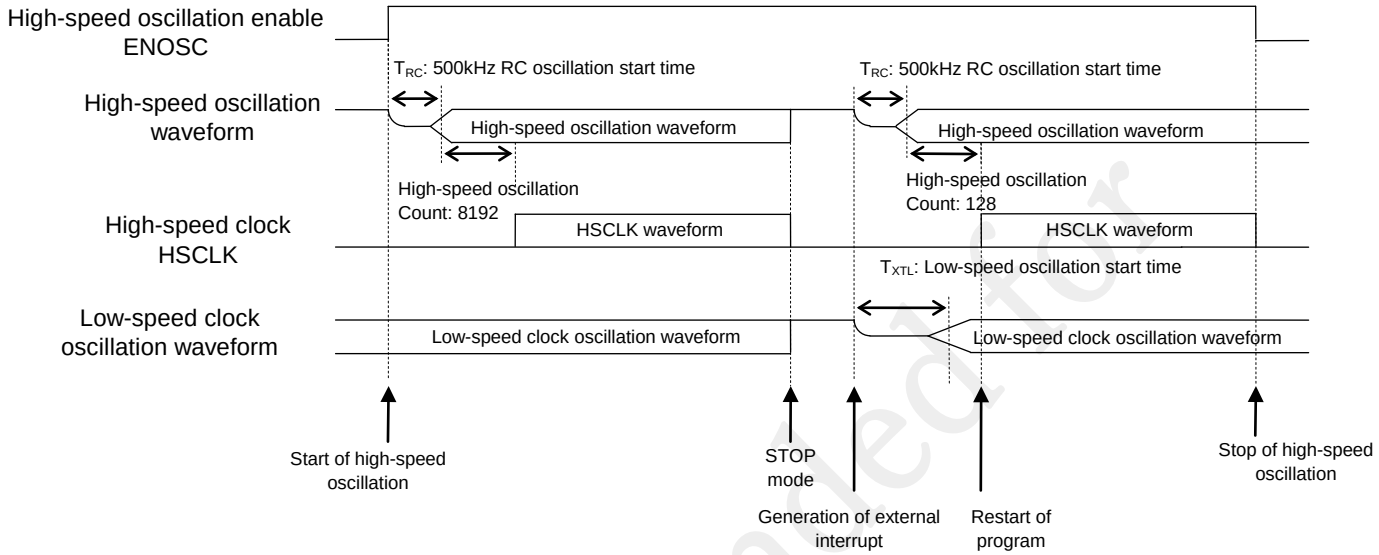

Figure 6-7 Operation of High-Speed Clock Generation Circuit in 500kHz RC Oscillation Mode

6.3.3 Switching of System Clock

The system clock can be switched between high-speed clock (HSCLK) and low-speed clock (LSCLK) by using the frequency control registers (FCON0, FCON1).
Figure 6-8 shows a flow of system clock switching processing (HSCLK→LSCLK) and Figure 6-11 shows a flow of system clock switching processing (LSCLK→HSCLK).

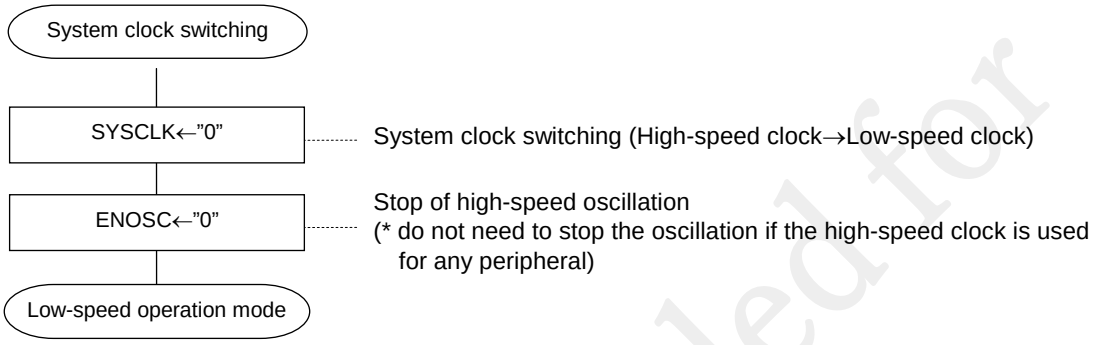

Figure 6-8 Flow of System Clock Switching Processing (HSCLK→LSCLK)

Note:
– After the power is turned on or if the system clock is switched from HSCLK to LSCLK immediately following return from the STOP mode, the CPU becomes inactive until LSCLK starts clock supply to the peripheral circuits. Therefore, It is recommended to switch to LSCLK after confirming that the LSCLK is oscillating by checking that the time base counter interrupt request bit (Q128H) is "1".

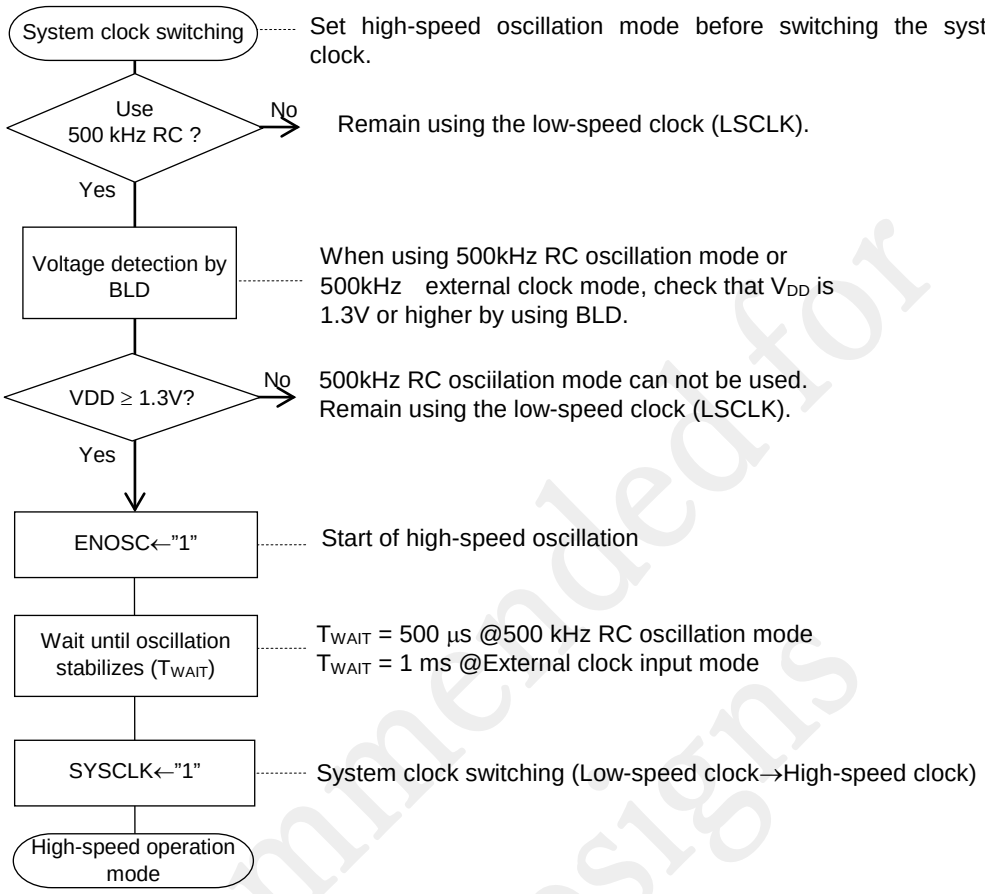

Figure 6-9 Flow of System Clock Switching Processing (LSCLK→HSCLK)

Note:
– If the system clock is switched from a low-speed clock to a high-speed clock before the high-speed clock (HSCLK) starts oscillation, the CPU becomes inactive until HSCLK starts clock supply to the peripheral circuits.

Time Base Counter

7. Time Base Counter

7.1 Overview

This LSI includes a low-speed time base counter (LTBC) and a high-speed time base counter (HTBC) that generate base clocks for peripheral circuits. By using the time base counter, it is possible to generate events periodically.
For input clocks, see Chapter 6, "Clock Generation Circuit". For interrupt permission, interrupt request flags, etc., described in this chapter, see Chapter 5, "Interrupts".

7.1.1 Features

- LTBC generates T32KHZ to T1HZ signals by dividing the low-speed clock (LSCLK) frequency.
- HTBC generates HTB1 to HTB32 signals by dividing the high-speed clock (HSCLK) frequency.
- LTBC allows frequency adjustment (Adjustment range: Approx. –488ppm to +488ppm. Adjustment accuracy: Approx. 0.48ppm) by using the low-speed time base counter frequency adjustment registers (LTBADJH and LTBADJL). (*[1])
- Capable of generating 128Hz , 32Hz , 16Hz , and 2Hz interrupts.

7.3 Description of Operation

7.3.1 Low-Speed Time Base Counter

The low-speed time base counter (LTBC) starts counting from 0000H on the LSCLK falling edge after system reset.
The T128HZ, T32HZ, T16HZ, and T2HZ outputs of LTBC are used as time base interrupts and an interrupt is requested on the falling edge of each output. Each of LTBC outputs is also used as an operation clock for peripheral circuits.
The output data of T128HZ to T1HZ of LTBC can be read from the low-speed time base counter register (LTBR). When reading the data, read LTBR twice and check that the two values coincide to prevent reading of undefined data during counting.
Figure 7-3 shows an example of program to read LTBR.

```
        LEA     offset LTBR     ; EA←LTBR address
MARK:
        L       R0,     [EA]    ; 1st read

;
            :
```

Figure 7-3 Programming Example for Reading LTBR

LTBR is reset when write operation is performed and the T128HZ to T1HZ outputs are set to "0". Write data is invalid. Since an interrupt occurs if a falling edge occurs in the T128Hz to T1Hz outputs during writing to LTBR, take care in software programming.
Figure 7-4 shows interrupt generation timing and reset timing of the time base counter output by writing to LTBR.

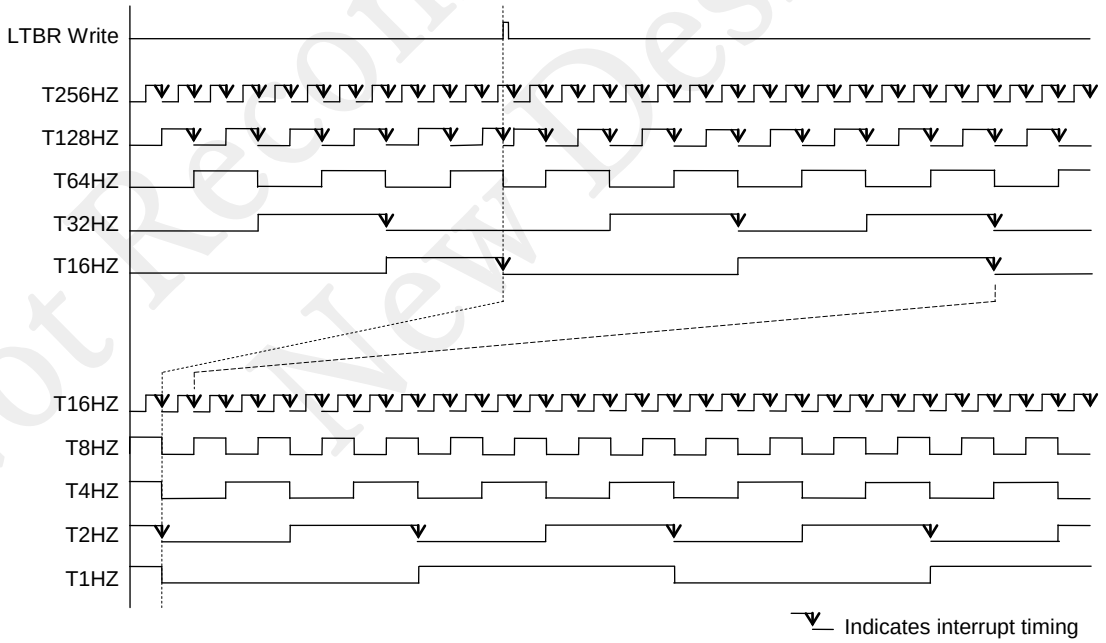

Figure 7-4 Interrupt Timing and Reset Timing by Writing to LTBR

7.3.2 High-Speed Time Base Counter

The high-speed time base counter is configured as a 4-bit 1/n counter (n = 1 to 16).
In the 4-bit 1/n counter, the divided clock (1/16×HSCLK to 1/1×HSCLK) selected by the high-speed time base counter divide register (HTBDR) is generated as HTBCLK. HTBCLK is used as a timer and also as an operation clock of PWM.
Figure 7-5 shows the output waveform of HTBCLK.

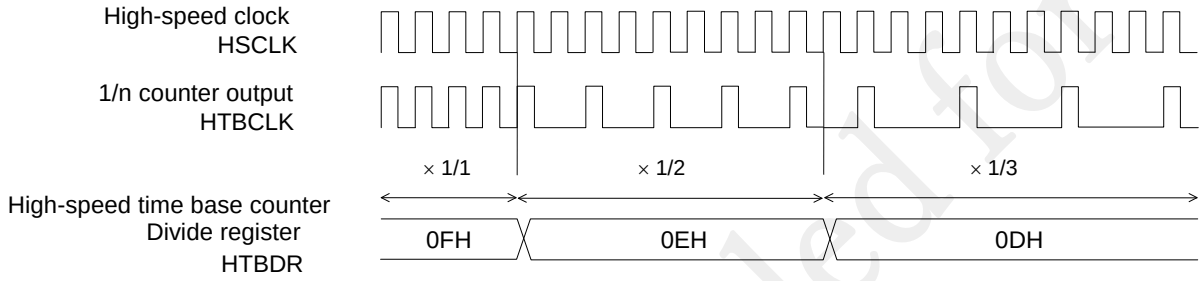

Figure 7-5 Output Waveform of HTBCLK

7.3.3 Low-Speed Time Base Counter Frequency Adjustment Function

Frequency adjustment (Adjustment range: Approx. –488ppm to +488ppm. Adjustment accuracy: Approx. 0.48ppm) is possible for outputs of T8KHZ to T1HZ of LTBC by using the low-speed time base counter frequency adjust registers (LTBADJH and LTBADJL).
Table7-1 shows correspondence between the frequency adjustment values (LTBADJH, LTBADJL) and adjustment ratio.

Table 7-1 Correspondence between Frequency Adjustment Values (LTBADJH, LTBADJL) and Adjustment Ratio

LADJ10 to 0											Hexadecimal	Frequency adjustment ratio (ppm)
0	1	1	1	1	1	1	1	1	1	1	3FFH	+487.80
0	1	1	1	1	1	1	1	1	1	0	3FEH	+487.33
:	:	:	:	:	:	:	:	:	:	:	:	:
0	0	0	0	0	0	0	0	0	1	1	003H	+1.43
0	0	0	0	0	0	0	0	0	1	0	002H	+0.95
0	0	0	0	0	0	0	0	0	0	1	001H	+0.48
0	0	0	0	0	0	0	0	0	0	0	000H	0
1	1	1	1	1	1	1	1	1	1	1	7FFH	–0.48
1	1	1	1	1	1	1	1	1	1	0	7FEH	–0.95
:	:	:	:	:	:	:	:	:	:	:	:	:
1	0	0	0	0	0	0	0	0	0	1	401H	–487.80
1	0	0	0	0	0	0	0	0	0	0	400H	–488.28

The adjustment values (LADJ10 to LADJ0) to be set in LTBADJH and LTBADJL can be obtained by using the following equations:

Adjustment value = Frequency adjustment ratio × 2097152 (decimal)
= Frequency adjustment ratio × 200000h (hexadecimal)

Example 1: When adjusting +15.0ppm (gaining time)
Adjustment value = +15.0ppm × 2097152 (decimal)
= $+15.0 \times 10^{-6} \times 2097152$
= +31.45728 (decimal)
≅ 01Fh (hexadecimal)

Example 2: When adjusting –25.5ppm (losing time)
Adjustment value = –25.5ppm × 2097152 (decimal)
= $-25.5 \times 10^{-6} \times 2097152$
= –53.477376 (decimal)
≅ 7CCh (hexadecimal)

Note:
The low-speed clock (LSCLK) and the outputs of T32KHZ and T16KHZ of LTBC are not adjusted by the frequency adjust function.
The frequency adjustment accuracy does not guarantee the accuracy including the frequency variation of the crystal oscillation (32.768kHz) due to temperature variations.

7.3.4 A signal generation for 16bit timer 2-3 frequency measurement mode

A signal (437C) used for 16bit timer 2-3 frequency measurement mode is generated in the time base conter block. See Chapter 10, "Timer" for more detail about the frequency measurement function.

Capture

8. Capture

8.1 Overview

This LSI has two channels of capture circuits that capture the T4KHZ to T32HZ signals of the low-speed base counter (LTBC) to the capture register at the occurrence of P00 and P01 interrupts. The circuits capture timings at which each interrupt occurred, based on the time from the time base counter.
For the external interrupt (P00INT, P01INT) from the P00 or P01 pin, see Chapter 5, "Interrupt" and Chapter 18, "Port 0".

[Description of Bits]

- **CAPF0** (bit 0)
  The CAPF0 bit is the flag to indicate whether data is captured in capture data register 0 (CARP0) or not.

- **CAPF1** (bit 1)
  The CAPF1 bit is the flag to indicate whether data is captured in capture data register 0 (CARP1) or not.
  When the CAPF0 bit is set to "1", it indicates that data is captured in capture data register 0 (CAPR1).
  When the CAPF1 bit is set to "1", the next capture operation is stopped. So perform the write operation to capture data register 1 (CAPR1) to clear theCAPF0 bit to "0".

CAPR0 is a register in which capture data is stored.
The T4KHZ to T32HZ signals of the low-speed time base counter (LTBC) are captured when the P00 interrupt request is generated with the CAPF0 flag (bit 0 of the CAPSTAT register) set to "0".
Writing to CAPR0 sets the CAPF0 flag of CAPSTAT to "0". The value of CAPR0 does not change even if data is written to it.

8.2.5 Capture Data Register 1 (CAPR1)

Address: 0F093H
Access: R/W

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

CAPR1 is a register in which capture data is stored.
The T4KHZ to T32HZ signals of the low-speed time base counter (LTBC) are captured when the P01 interrupt request is generated with the CAPF1 flag (bit 1 of the CAPSTAT register) set to "0".
Writing to CAPR1 sets the CAPF1 flag of CAPSTAT to "0". The value of CAPR1 does not change even if data is written to it.

8.3 Description of Operation

The capture circuit starts the capture operation by setting the ECAP0 or ECAP1 bit of the capture control register (CAPCON).
When the input trigger from the P00 or P01 pin selected by the external interrupt control register 0 or 1 (EXICON0 or EXICON1) is generated and the P00 or P01 interrupt request flag (QP00 or QP01) is set to "1", the T4KHZ to T32HZ signals of the low-speed time base counter (LTBC) are captured in the capture register 0 or 1 (CAPR0 or CAPR1) on the next low-speed clock (LSCLK) falling edge and the at the same time, the capture flag (CAPF0 or CAPF1) of the capture status register (CAPSTAT) is set to "1".
When the capture flag (CAPF0, CAPF1) is "1", the following capture operation stops.
After reading the value captured in the capture register 0 or 1 (CAPR0, CAPR1), perform write operation (write data is meaningless) for the capture register 0 or 1 (CAPR0, CAPR1), clear the capture flag (CAPF0, CAPF1) to "0", and wait for the next P00 or P01 interrupt.
Figure 8-2 shows the timing of the capture operation.

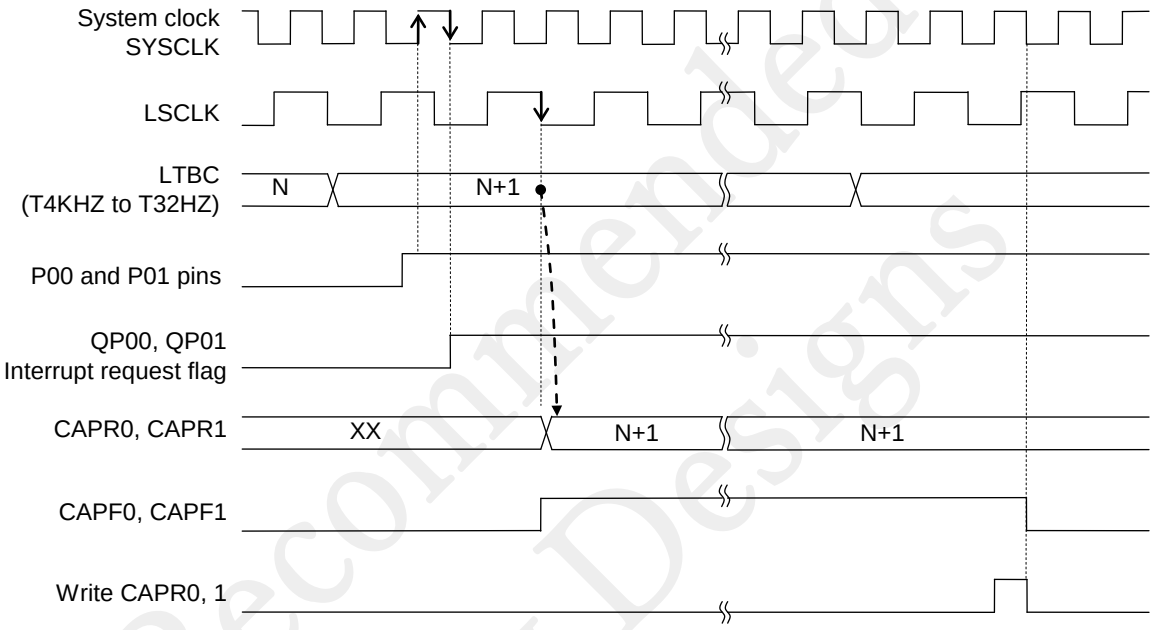

Figure 8-2 Timing Diagram of Capture Operation

Note:
When CPU is operating at the high speed (HSCLK), check that the capture flag (CAPF0, CAPF1) is set to "1" after the P00 or P01 interrupt request is generated and then read capture data register 0 or 1 (CAPR0, CAPR1).

1 kHz Timer (1kHzTM)

9. 1 kHz Timer (1kHzTM)

9.1 Overview

This LSI includes a 1 kHz timer to measure 1/1000 seconds.
The 1 kHz timer counts the 1 kHz(1.024kHz) signal created by dividing the T2KHZ output frequency (2.048kHz) of the low-speed time base counter (LTBC) and generates a 10 Hz or 1 Hz interrupt (1 kHz timer interrupt).
With the 1 kHz timer, 1/1000 second, which is difficult to generate on a time-base-counter basis, represented by a decimal number can be obtained easily. The timer can be applied to period measurement for stopwatches.
For the timer base counter, see Chapter 7, "Time Base Counter".

T1KSEL	Description

9.3 Description of Operation

By setting the T1KRUN bit of the 1kHz timer control register (T1KCON) to "1", the 1kHz timer starts counting of the 1kHz timer counter registers L or H (T1KCRL, T1KCRH).
By dividing the T2KHz signal frequency (2.048kHz) of the low-speed timer base counter (LTBC) by the binary/ternary counter, the timer generates a 1kHz signal. Based on the 1kHz signal, a 1kHz timer interrupt request signal (T1KINT) is generated by the decimal counters of T1KCRL and T1KCRH. The period of the 1kHz timer interrupt can be selected between the 10Hz interrupt or 1Hz interrupt using the T1KSEL bit of T1KCON.
When write operation is performed for T1KCRL or T1KCRH, the value of the binary/ternary counter and the value of T1KCRL or T1KCRH is cleared to "0".
Data can be read from T1KCRL and T1KCRH. When reading data from T1KCRL or T1KCRH in the 1kHz timer operation start state, read T1KCRL or T1KCRH twice and check that the values match to prevent the reading of undefined data during counting.

For the input clock, see Chapter 6, "Clock Generation Circuit".

10.1.1 Features

- The timer interrupt (TMnINT) is generated when the values of timer counter register (TMnC, n=0 to 3) and timer data register (TMnD) coincide.
- A timer configured by combining timer 0 and timer 1 or timer 2 and timer 3 can be used as a 16-bit timer.
- For the timer clock, the low-speed clock (LSCLK), high-speed time base clock (HTBCLK), or external clock can be selected.
- A 16bit-timer 2 & 3 has clock frequency measurement mode, which can count HTBCLK and generates the timer interrupt (TM3INT) when the count ends. Using the count data to know the frequency by software can determine more accurate baud-rate.

10.3 Description of Operation

10.3.1 Timer mode operation

The timer counters (TMnC) are set to an operating state (TnSTAT are set to "1") on the first falling edge of the timer clocks (TnCK) that are selected by the Timer 0 to 3 control register 0 (TMnCON0) when the TnRUN bits of timer 0 to 3 control register 1 (TMnCON1) are set to "1" and increment the count value on the 2nd falling.

When the count value of TM0 to TM3C and the timer 0 to 3 data register (TMnD) coincide, timer 0 to 3 interrupt (TMnINT) occurs on the next timer clock falling edge, TMnC are reset to "00H" and incremental counting continues.

When the TnRUN bits are set to "0", TMnC stop counting after counting once the falling of the timer clock (TnCK). Confirm that TMnC has been stopped by checking that the TnSTAT bit of the Timer 0–3 control register 1 (TMnCON1) is "0". When the TnRUN bits are set to "1" again, TMn restart incremental counting from the previous values. To initialize TMnC to "00H", perform write operation in TMnC.
The timer interrupt period (TTMI) is expressed by the following equation.

$$TTMI = \frac{TMnD + 1}{TnCK\ (Hz)} \quad (n = 0 \text{ to } 3)$$

TMnD: Timer 0 to 3 data register (TMnD) setting value (01H to 0FFH)
TnCK: Clock frequency selected by the Timer 0 to 3 control register 0 (TMnCON0)

After the TnRUN bits are set to "1", timers are synchronized by the timer clock and counting starts so that an error of a maximum of 1 clock period occurs until the first timer interrupt. The timer interrupt periods from the second time are constant.
Figure 10-2 shows the operation timing diagram of Timer 0 to 3.

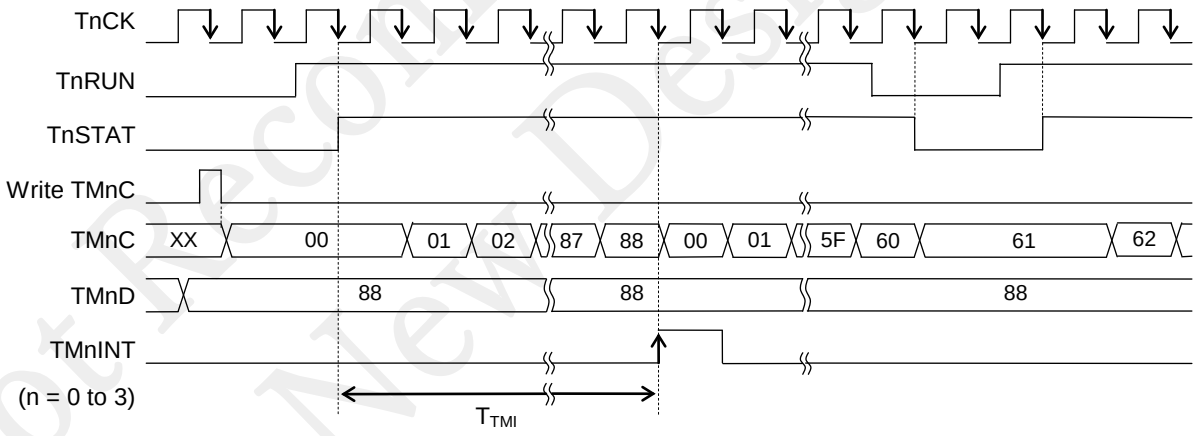

Figure 10-2 Operation Timing Diagram of Timer 0 to 3

Note:
Even if "0" is written to the TnRUN bits, counting operation continues up to the falling edge (the timer 0 to 3 status flag (TnSTA) is in a "1" state) of the next timer clock pulse. Therefore, the timer 0 to 3 interrupt (TMnINT) may occur.

10.3.2 16-bit timer frequency measurement mode operation

The frequency measurement mode in 16-bit timer 2&3, is used to count the frequency of 500kHz RC oscillation clock which typically has temperature variation and production tolerance.

Using the frequency measurement mode can make better accuracy for uart baud-rate clock or timer function.
(1) Reading the count data, caluculating and setting it to uart communication baud-rate registers, can make more accurate baud-rate clock.
(2) Reading the count data, caluculating and setting it to a timer data register, can make more accurate timing in normal timer mode.

Figure 10-3 shows the operation timing in frequency measurement mode.

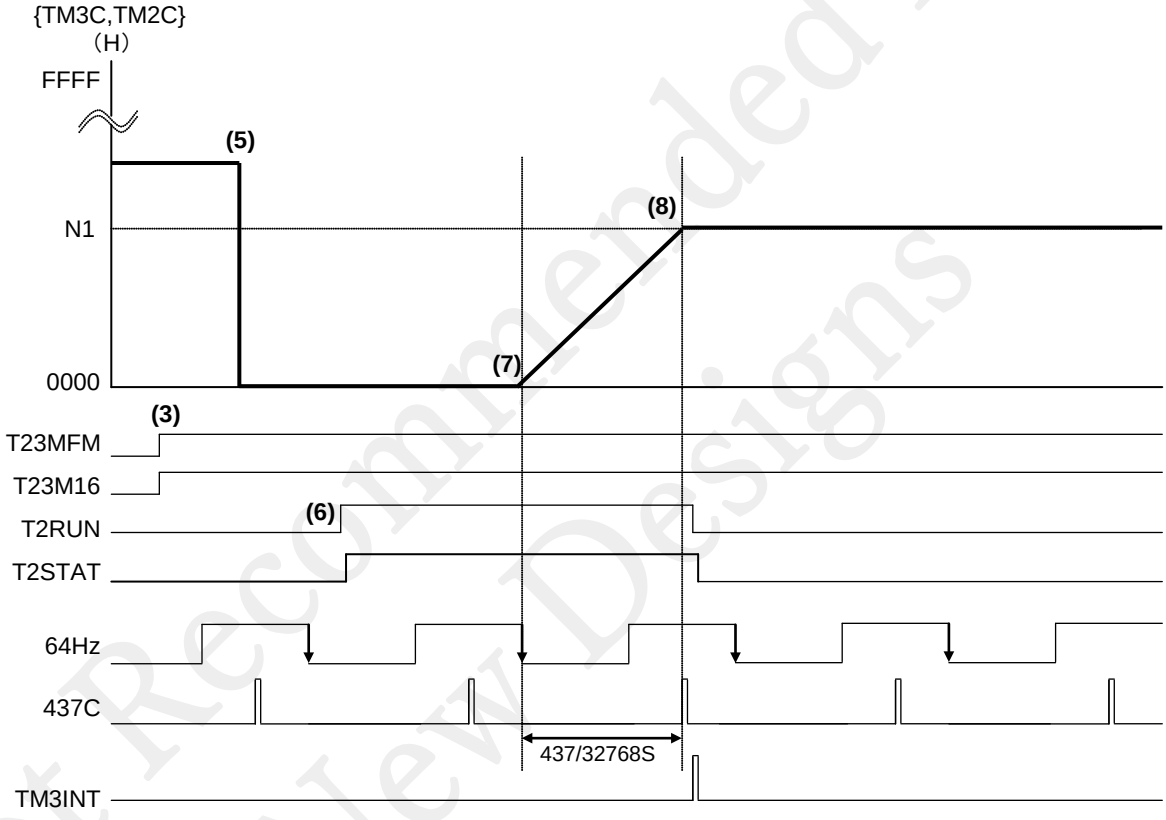

Figure 10-3 Operation Timing in frequency measurement mode

(1) High-speed clock (HSCLK, HTBCLK) has to be in oscillating state by conrolling with FCONn registers. And also set HTBDR register (High-speed Time Base counter Devide Register) per necessory.

(2) Reset both T2RUN bit (bit0 of TM2CON1 register) and T3RUN bit (bit0 of TM3CON1 register) to "0" to stop the timer. And then, check both T2STAT bit (bit7 of TM2CON1 register) and T3STAT bit (bit7 of TM3CON1 register) are "0" for making certain the timer stops.

(3) Set T23MFM bit (bit3 of TM2CON0 register) to "1" (Frequency measurement mode), set T23M16 bit (bit2of TM2CON0 register) to "1" (16bit mode) and set T2CS1-0 bits(bit1/0 of TM2CON0 register) to "01"(HTBCLK mode).

(4) Set "FFH" to both TM2D register and TM3D register.

(5) Clear both TM2C register and TM3C register to "00H".

(6) Set T2RUN bit (bit0 of TM2CON1 register) to "1" to start counting the timer.

(7) On the condition of (T23MFM bit=="1") & ((TM23M16 bit=="1") & (T2RUN bit=="1"), the count-up starts at rising edge of 64Hz clock signal.

(8) The count-up stops at the falling edge of the next timer clock (HTBCLK) after 437C signal becomes "1". Also, at the same time, T2RUN bit and T2STAT bit become "0" and the interrupt signal TM3INT activates.

(9) After checking T2STAT bit or TM3INT interrupt occurs, read out the data (N1) of TM2C register and TM3C register.

For example of utilizing N1, to occur 9600Hz timer interrupt.

Assuming the HTBCLK is 600kHz,
N1 = 600000 * 437 / 32768
= 8001 (Decimal)
= 1F41 (Hexadecimal)
= 0001 1111 0100 0001 (Binary)

As (437 / 32768) sec is equivalent to 128 clocks at 9600Hz (more precisely, 9598Hz), a division of the count N1 by 128 equals frequency ratio (N2) between the frequency of HTBCLK and 9600Hz.
Because $128 = 2^7$, that caluculation can be determined by truncating the righthand seven digits of N1(Binary).
N2 = 8001(Decimal) / 128 (Decimal)
=0001 1111 0 (Binary)
=3E (Hexadecimal)
=62 (Decimal)

This indicates that 9600Hz is about 62 times the cycle of HTBCLK.
Therefore, if 3DH(=3EH-1) set to the timer register and the timer start counting, the cycle of TMnINT interrupt that can occur every 62 counts of HTBCLK is:
tTMnINT = (1 / 600000) * 62 = 0.10333ms (9677Hz)

10.3.3 16-bit timer frequency measurement mode application for setting uart baud-rate

For example, when the target baud-rate is 9600bps and the clock is HSCLK(500kHz), the UART0 baud-rate register (UA0BRTH, UA0BRTL) should be set as follows. See Section 14.3.2. in UART chapter.
UA0BRTH, UA0BRTL = 500000/9600 - 1 = 51 (decimal) = 33(Hexadecimal)

However, actual 500kHz RC oscillation clock has temperature variation and production tolerance, the calculation by using the fixed value of 500kHz can not make accurate baud-rate. To compensate it, count the frequency in the frequency measurement mode to set the baud-rate again before operating UART communication.

After finishing the clock count in the frequency measurement mode, assuming HTBCLK is 451kHz, data of TM2C register and TM3C register will be:

N1 = 451000 * 437 / 32768
= 6014 (Decimal)
= 177E (Hexadecimal)
= 101110<u>1111110 (Binary)</u>

As (437 / 32768) sec is equivalent to 128 clocks at 9600Hz (more precisely, 9598Hz), a division of the count (N1) by 128 equals frequency ratio (N2) between the frequency of HTBCLK and 9600Hz.
For the calculation, the accuracy of baud-rate depends on truncating (1) or rounding (2) the data.

UA0BRTH regiser and UA0BRTL register have to be set as follows. See the previous secntion 10.3.2. and section 14.3.2. in UART chapter.
UA0BRTH, UA0BRTL = (the frequency ratio of HTBCLK and 9600Hz) - 1 = (N1/128)-1 = N2 -1

(1) Round data in caluculation
N1 = 101110<u>1111110 (binary)</u>
N2 = 101111 (binary) = 47 (decimal) = 2F (hexadecimal)
Set N2-1 (= 2E) to UA0BRTH and UA0BRTL registers.
In this case, the acual baud-rate will be 9595.744681.. [bps], so the accuracy = ((9595.744681/9600) -1)* 100= -0.04..[%].

(2) Trancate data in calucuation (the accuracy of baud-rate becomes worse)
N1 = 101110<u>1111110 (binary)</u>
N2 = 101110 (binary) = 46 (decimal) = 2E (hexadecimal)
Set N2-1 (= 2D) to UA0BRTH and UA0BRTL registers.
In this case, the acual baud-rate will be 9804.347826.. [bps], so the accuracy = ((9804.347826/9600) -1)* 100= 2.12..[%].

11.1 Overview

This LSI includes one channel of 16-bit PWM (Pulse Width Modulation).
The PWM output (PWM0) function is assigned to P43(Port 4) and P34(Port 3) as the tertiary function. For the functions of port 4 and port3, see Chapter 21, "Port 4" and Chapter 20, "Port 3".

When data is read from PW0CL, the value of PW0CH is latched. When reading PW0CH and PW0CL, use a word type instruction or pre-read PW0CL.

The contents of PW0CH and PW0CL during PWM operation cannot be read depending on the combination of the PWM clock and system clock. Table 11-1 shows PW0CH and PW0CL read enable/disable for each combination of the PWM clock and system clock.

1	PWM0 output flag = "1" (initial value)

- **P0STAT** (bit 7)
  The P0STAT bit indicates "counting stopped or "counting in progress" of PWM0.

P0STAT	Description
0	Counting stopped. (Initial value)
1	Counting in progress.

11.3 Description of Operation

The PWM0 counter registers (PW0CH, PW0CL) are set to an operating state (P0STAT is set to "1") on the first falling edge of the PWM clock (P0CK) that are selected by the PWM0 control register 0 (PW0CON0) when the P0RUN bit of PWM0 control register 1 (PW0CON1) is set to "1" and increment the count value on the 2nd falling edge.

When the count value of PWM0 counter registers and the value of the PWM0 duty buffer (PW0DBUF) coincide, the PWM flag (P0FLG) is set to "0" on the next timer clock falling edge of P0CK.
When the count value of PWM0 counter registers and the value of the PWM0 period buffer (PW0PBUF) coincide, the PWM flag (P0FLG) is set to "1" on the next falling edge of P0CK and PWM0 counter registers is set to "0000H" and incremental counting continues. At the same time, the value of the PWM0 duty register (PW0DH, PW0DL) is transferred to the PWM0 duty buffer (PW0DBUF) and the value of PWM0 period register (PW0PH, PW0PL) to the PWM0 period buffer (PW0PBUF).

When the P0RUN bit is set to "0", PWM0 counter registers stop counting after counting once the falling of the PWM clock (P0CK). Confirm that PW0CH and PW0CL are stopped by checking that the PnSTAT bit of the PWM0 control register 1 (PW0CON1) is "0". When the P0RUN bit is set to "1" again, PWM0 counter registers restarts incremental counting from the previous value on the falling edge of P0CK.

To initialize PWM0 counter registers to "0000H", perform write operation in either of PW0CH or PW0CL. At that time, P0FLG is also set to "1". When data is written in the PWM0 duty register (PW0DH, PW0DL) during count stop (P0RUN is in a "1" state), the data is transferred to the PWM0 duty buffer (PW0DBUF) and when data is written in the PWM0 period register (PW0PH, PW0PL), the data is transferred to the PWM0 period buffer (PW0PBUF).

The PWM clock, the point at which an interrupt of PWM0 occurs, and the logic of the PWM output are selected by PWM0 control register 0 (PW0CN0).

The period of the PWM0 signal (TPWP) and the first half duration (TPWD) of the duty are expressed by the following equations.

$$T_{PWP} = \frac{PW0P + 1}{P0CK\ (Hz)}$$

$$T_{PWP} = \frac{PW0D + 1}{P0CK\ (Hz)}$$

PW0P: PWM0 period registers (PW0PH, PW0PL) setting value (0001H to 0FFFFH)
PW0D: PWM0 duty registers (PW0DH, PW0DL) setting value (0000H to 0FFFEH)
P0CK: Clock frequency selected by the PWM0 control register 0 (PW0CON0)

After the P0RUN bit is set to "1", counting starts in synchronization with the PWM clock. This causes an error of up to 1 clock pulse to the time the first PWM interrupt is issued. The PWM interrupt period from the second time is fixed.
Figure 11-2 shows the operation timing of PWM0.

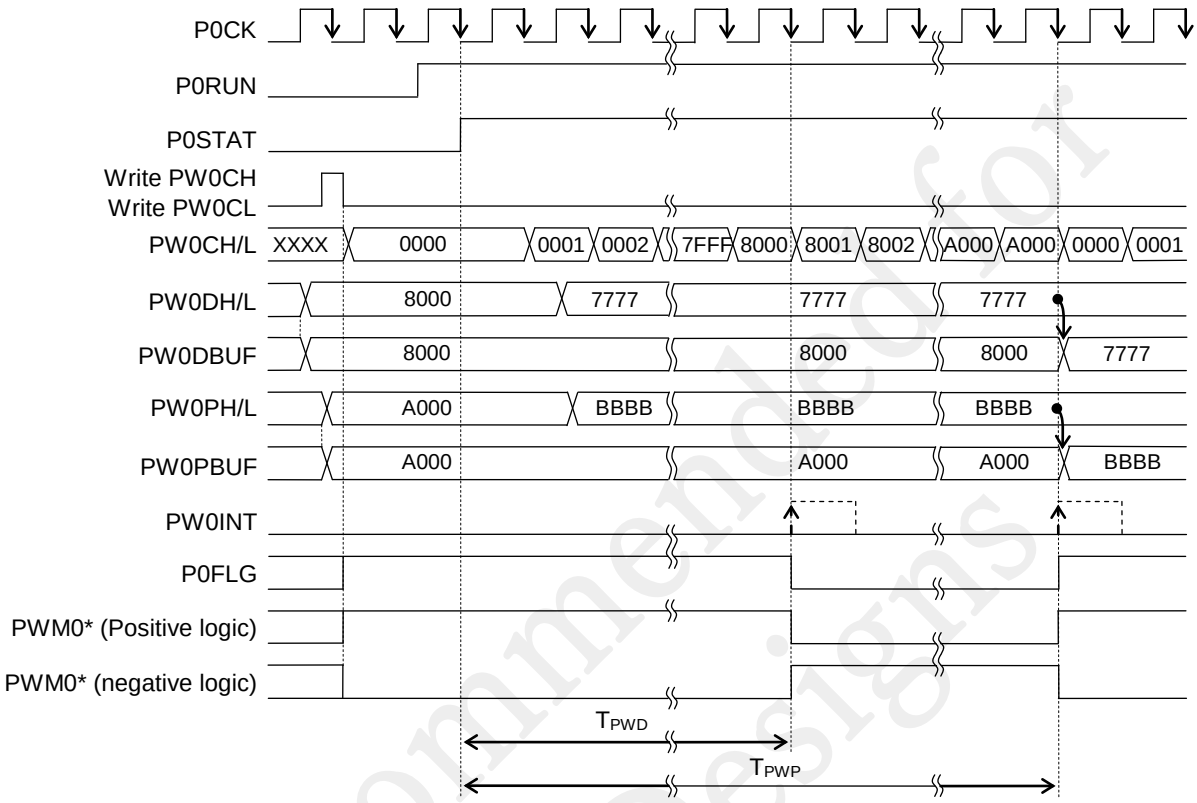

Figure 11-2 (1/2) Operation Timing Diagram of PWM0

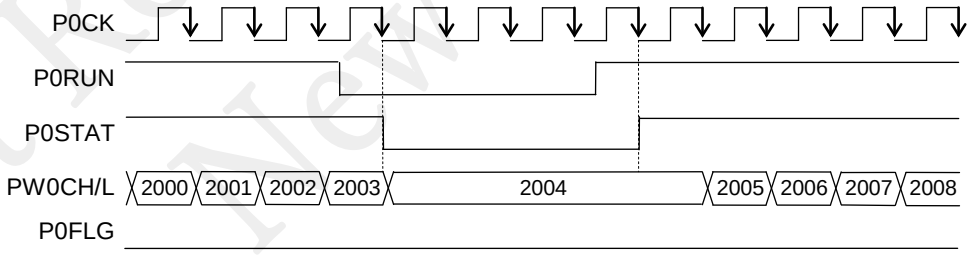

Figure 11-2 (2/2) Operation Timing Diagram of PWM0

Note:
Even if "0" is written to the P0RUN bit, counting operation continues up to the falling edge (the PWM0 status flag (P0STAT) is in a "1" state) of the next PWM clock pulse. Therefore, the PWM0 interrupt (PW0INT) may occur.

Watchdog Timer

12. Watchdog Timer

12.1 Overview

This LSI incorporates a watchdog timer (WDT) that operates at a system reset unconditionally (free-run operation) in order to detect an undefined state of the MCU and return from that state.
If the WDT counter overflows due to the failure of clearing of the WDT counter within the WDT overflow period, the watchdog timer requests a WDT interrupt (non-maskable interrupt). When the second overflow occurs, the watchdog timer generates a WDT reset signal and shifts the mode to a system reset mode.
For interrupts see Chapter 5, "Interrupts," and for WDT interrupt see Chapter 3, "Reset Function".

12.1.1 Features

- Non-maskable interrupt
- Free running (cannot be stopped)
- One of four types (125ms, 500ms, 2s, 8s) of overflow periods selectable by software
- Reset generated by the second overflow

12.1.2 Configuration

Figure 12-1 shows the configuration of the watchdog timer.

12.2.2 Watchdog Timer Control Register (WDTCON)

Address: 0F00EH
Access: R/W
Access size: 8 bits
Initial value: 00H

	7	6	5	4	3	2	1	0
WDTCON	d7	d6	d5	d4	d3	d2	d1	WDP/d0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

WDTCON is a special function register (SFR) to clear the WDT counter.
When WDTCON is read, the value of the internal pointer (WDP) is read from bit 0.

[Description of Bits]

- **WDP/d0** (bit 0)
  The value of the internal pointer (WDP) is read from this bit. The WDP is reset to "0" at the system reset or Watch Dog Timer overflow and is inverted every writing to WDTCON.

- **d7-d0** (bits 7-0)
  This bit is used to write data to clear the WDT counter. Write "5AH" on the condition of WDP is "0" and write "0A5H" on the condition of WDP is "1".

Note:
Writing to WDTCON becomes enable after the system reset or releasing STOP mode and then the low-speed clock (LSCLK) oscillation starts. Untill the low-speed clock oscillation start, the WDP will not be inverted even if writing to the WDTCON. Therefore, please check the WDP before writing to the WDTCON to determine writing "5AH" or "0A5H".

Program example

```
if ( WDP == 1 ){
    WDTCON = 0xa5;      /* WDP : 1 -> 0 */
}
WDTCON = 0x5a;          /* WDP : 0 -> 1 */
WDTCON = 0xa5;          /* WDP : 1 -> 0 */
```

12.2.3 Watchdog Timer Mode Register (WDTMOD)

Address: 0F00FH
Access: R/W
Access size: 8 bits
Initial value: 02H

	7	6	5	4	3	2	1	0
WDTMOD	—	—	—	—	—	—	WDT1	WDT0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	1	0

WDTMOD is a special function register to set the overflow period of the watchdog timer.

[Description of Bits]

- **WDT1-0** (bits 1-0)
  These bits are used to select an overflow period of the watchdog timer.
  The WDT1 and WDT0 bits set a overflow period (TWOV) of the WDT counter. One of 125ms, 500ms, 2s, and 8s can be selected.

WDT1	WDT0	Description
0	0	125 ms
0	1	500 ms
1	0	2 s (initial value)
1	1	8 s

12.3 Description of Operation

The WDT counter starts counting after the system reset has been released and the low-speed clock oscillation start..
Write "5AH" when the internal pointer (WDP) is "0"and then the WDT counter is cleared by writing "0A5H" when WDP is "1".
WDP is reset to "0" at the time of system reset or when the WDT counter overflows and is inverted whenever data is written to WDTCON.
When the WDT counter cannot be cleared within the WDT counter overflow period (T_{WOV}), a watchdog timer interrupt (WDTINT) occurs. If the WDT counter is not cleared even by the software processing performed following the watchdog timer interrupt and overflow occurs again, WDT reset occurs and the mode shifts to a system reset mode.
For the overflow period (TWOV) of the WDT counter, one of 125ms, 500ms, 2s, and 8s can be selected by the watchdog mode register (WDTMOD).
Clear the WDT counter within the clear period of the WDT counter shown in Table 12-1.

Table 12-1 Clear Period of WDT Counter

WDT1	WDT0	T_{WOV}	T_{WCL}
0	0	125 ms	Approx. 121 ms
0	1	500 ms	Approx. 496 ms
1	0	2000 ms	Approx. 1996 ms
1	1	8000 ms	Approx. 7996 ms

Figure 12-2 shows an example of watchdog timer operation.

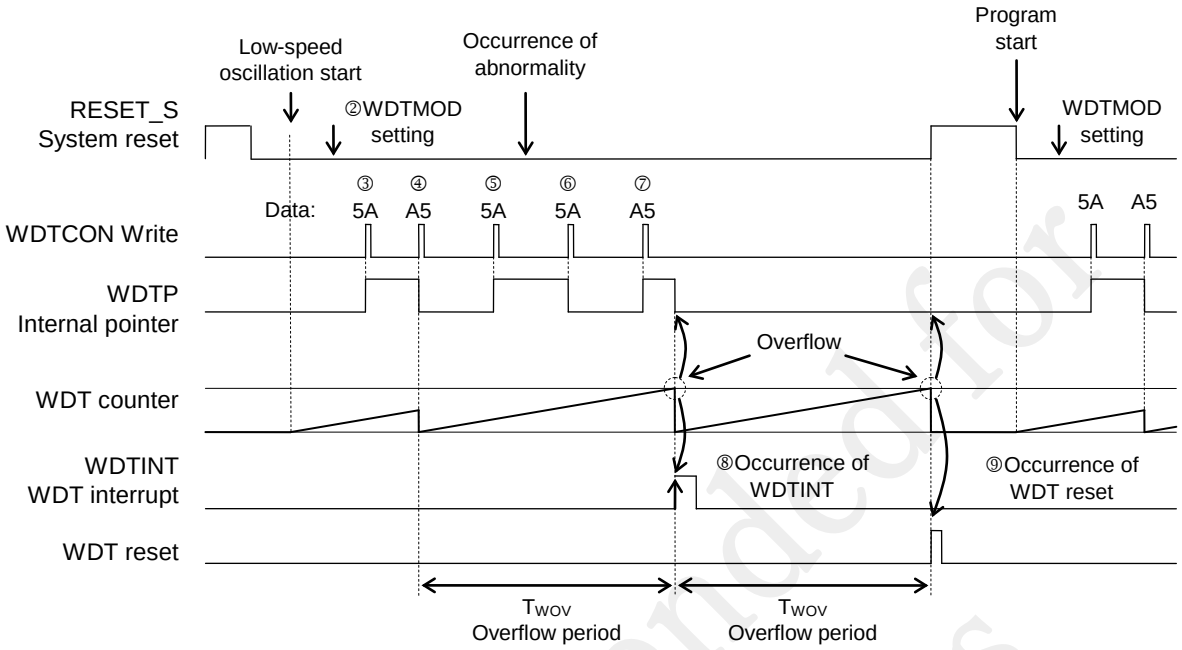

Figure 12-2 Example of Watchdog Timer Operation

① The WDT counter starts counting after the system reset has been released and the low-speed clock oscillation start.
② The overflow period of the WDT counter (TWOV) is set to WDTMOD.
③ "5AH" is written to WDTCON. (Internal pointer 0→1)
④ "0A5H" is written to WDTCON and the WDT counter is cleared. (Internal pointer 1→0)
⑤ "5AH" is written o WDTCON. (Internal pointer 0→1)
⑥ When "5AH" is written to WDTCON after the occurrence of abnormality, it cannot be accepted as the internal pointer is set to "1". (Internal pointer 1→0)
⑦ Although "0A5H" is written to WDTCON, the WDT counter is not cleared since the internal pointer is "0" and the writing of "5AH" is not accepted in ⑥. (Internal pointer 0→1)
⑧ The WDT counter overflows and a watchdog timer interrupt request (WDTINT) is generated. In this case, the internal pointer is cleared to "0".
⑨ If the WDT counter is not cleared even by the software processing performed following a watchdog timer interrupt and the WDT counter overflows again, WDT reset occurs and the mode is shifted to a system reset mode.

Note:
- In STOP mode, the watchdog timer operation also stops.
- In HALT mode, the watchdog timer operation does not stop. When the WDT interrupt occurs, the HALT mode is released.
- The watchdog timer cannot detect all the abnormal operations. Even if the CPU loses control, the watchdog timer cannot detect the abnormality in the operation state in which the WDT counter is cleared.

13.3 Description of Operation

13.3.1 Transmit Operation

When "1" is written to the S0MD1 bit and "0" is written to the S0MD0 bit of the serial mode register (SIO0MOD0), this LSI is set to a transmit mode.
When transmit data is written to the serial port transmit /receive buffer (SIO0BUFL and H) and the S0EN bit of the serial port control register (SIO0CON) is set to "1", transmission starts. When transmission of 8/16-bit data terminates, a synchronous serial port interrupt (SIO0INT) occurs and the S0EN bit is set to "0".
Transmit data is output from the tertiary function pins (P42/SOUT0 or P46/SOUT0) of GPIO.
When an internal clock is selected in the serial port mode register (SIO0MOD1), the LSI is set to a master mode and when an external clock (P41/SCK0 or P45/SCK0) is selected, the LSI is set to a slave mode.
The serial port mode register (SIO0MOD0) enables selection of MSB first/LSB first.
The transmit data output pin (P42/SOUT0 or P46/SOUT0) and transfer clock input/output pin (P41/SCK0 or P45/SCK0) must be set to the tertiary functions.
Figures 13-2 and 13-3 show the transmit operation waveforms of the synchronous serial ports for clock type 0 and clock type 1, respectively (8-bit length, LSB first, clock types 0 and 1).

13.3.2 Receive Operation

When "0" is written to the S0MD1 bit and "1" is written to the S0MD0 bit of the serial mode register (SIO0MOD0), this LSI is set to a receive mode.
When the S0EN bit of the serial port control register (SIO0CON) is set to "1", reception starts. When reception of 8/16-bit data terminates, a synchronous serial port interrupt (SIO0INT) occurs and the S0EN bit is set to "0".

When "1" is written to the S0MD1 bit and "1" is written to the S0MD0 bit of the serial mode register (SIO0MOD0), this LSI is set to a transmit/receive mode.
When the S0EN bit of the serial port control register (SIO0CON) is set to "1", transmission/reception starts. When transmission/reception of 8/16-bit data terminates, a synchronous serial port interrupt (SIO0INT) occurs and the S0EN bit is set to "0".
Receive data is input from the tertiary function pins (P40/SIN0 or P44/SIN0) of GPIO, and transmit data is output from the tertiary function pins (P42/SOUT0 or P46/SOUT0) of GPIO

UA0BUF is a special function register (SFR) to store the transmit/receive data of the UART.
In transmit mode, write transmission data to UA0BUF. To tranmit data continuously, write the next data to UA0BUF after making sure that the U0FUL flag of the UART0 status register (UA0STAT) is "0". Any value written to UA0BUF can be read.
In receive mode, since data received at termination of reception is stored in UA0BUF, read the contents of UABUF using the UART0 interrupt at termination of reception. At continuous reception, BA0BUF is updated whenever reception terminates. Any write to BA0BUF is disabled in receive mode.
The bits not required when 5-bit, 6-bit, 7-bit, or 8-bit data length is slected become invalid in transmit mode and are set to "0" in receive mode.

Note:
For operation in transmit mode, be sure to set the transmit mode (UA0MOD0 and UA0MOD1) before setting transmit data in UAOBUF.

14.3 Description of Operation

14.3.1 Transfer Data Format

In the transfer data format, one frame contains a start bit, a data bit, a parity bit, and a stop bit. In this format, 5 to 8 bits can be selected as data bit. For the parity bit, "with parity bit", "without parity bit", "even parity", or "odd parity" can be selected. For the stop bit, "1 stop bit" or "2 stop bits" are available and for the transfer direction, "LSB first" or "MSB first" are available for selection. For serial input/output logic, positive logic or negative logic can be selected. All these options are set with the UART0 mode register (UA0MOD1).
Figure 14-2 and Figure 14-3 show the positive logicc input/output format and negative logic input/output format, respectively.

14.3.2 Baud Rate

Baud rates are generated by the baud generator.
The baud rate generator generates a baud rate by counting the clock selected by the baud rate clock selection bits (U0CK1, U0CK0) of the UART0 mode register 0 (UA0MOD0). The count value of the baud rate generator can be set by writing it in the UART0 baud rate register H or L (UA0BRTH, UA0BRTL). The maximum count is 4096.
The setting values of UA0BRTH and UA0BRTL are expressed by the following equation.

$$\text{UA0BRTH, L} = \frac{\text{Clock frequency (Hz)}}{\text{Baud rate (bps)}} - 1$$

Table 14-2 lists the count values for typical baud rates.

Table 14-2 Count Values for Typical Baud Rates

Baud rate	Baud rate generator clock selection			Count value of the baud rate generator			
	Baud rate clock	U0CK1	U0CK0	Count value	Period of 1 bit	UA0BRTH	UA0BRTL
1200 bps	32.768 kHz	0	0	27	Approx. 824 μs	00H	1AH
2400 bps	65.536 kHz	0	1	27	Approx. 412 μs	00H	1AH
4800 bps	500kHz	1	*	104	Approx. 208 μs	00H	067H
9600 bps	500kHz	1	*	52	Approx. 104 μs	00H	033H
19200 bps	500kHz	1	*	26	Approx. 52 μs	00H	01BH
38400 bps	500kHz	1	*	13	Approx. 26 μs	00H	00CH
57600 bps	500kHz	1	*	9	Approx. 18 μs	00H	008H

Note:
- When UA0BRTH or UA0BRTL is set to a value equal to less than "0007H", the value set is read from UA0BRTH or UA0BRTL but the value of the baud rate clock counter is the same as the value when UA0BRTH or UA0BRTL is set to "0008H".
- When specifying 65.536 kHz (LSCLK×2) for the clock, enable the operation of the 2×low-speed clock by setting bit 2 (ENMLT) of the frequency control register 1 (FCON1) to "1".
- Compensating tolerant of RC oscillation 500kHz with Timer can support errors of +/- 2% or less at 9600bps. See Section 10.3.2., "Frequency measurement mode".

14.3.3 Transmit Data Direction

Figure 14-4 shows the relationship between the transmit/receive buffer and the transmit/receive data.

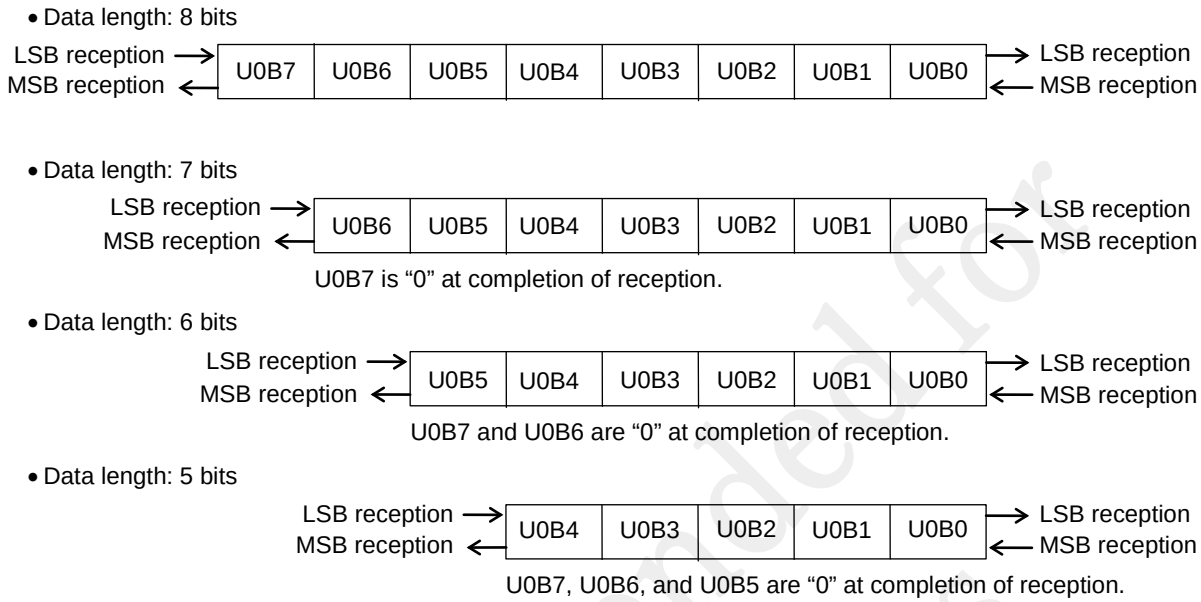

Figure 14-4 Relationship between Transmit/Receive Buffer and Transmit/Receive Data

Note:
When the TXD0 pin is set to serve the secondary function output in receive mode, "H" level is output from the TXD0 pin.

14.3.4 Transmit Operation

Transmission is started by setting the U0IO bit of the UART0 mode register 0 (UA0MOD0) to "0" to select transmit mode and setting the U0EN bit of the UART0 control register (UA0CON) to "1".
Figure 14-5 shows the operation timing for transmission.

When the U0EN bit is set to "1" (①), the baud rate generator generates an internal transfer clock of the baud rate set and starts transmission.
The start bit is output to the TXD0 pin by the falling edge of the internal transfer clock (②). Subsequently, transmit data, a parity bit, and a stop bit are output.
When the start bit is output (②), a UART0 interrupt is requested. In the UART0 interrupt routine, the next data to be transmitted is written to the transmit/receive buffer (UA0BUF).
When the next data to be transmitted is written to the transmit/receive buffer (UA0OBUF), the transmit buffer status flag (U0FUL) is set to "1" (③) and a UART0 interrupt is requested on the falling edge of the internal transfer clock (④) after transmission of the stop bit. If the UART0 interrupt routine is terminated without writing the next data to the transmit/receive buffer, the U0FUL bit is not set to "1" (⑤) and transmission continues up to the transmission of the stop bit, then the U0EN bit is reset to "0" and a UART0 interrupt is requested.
The valid period for the next transmit data to be written to the transmit/receive buffer is from the generation of an interrupt to the termination of stop bit transmission. (⑥)

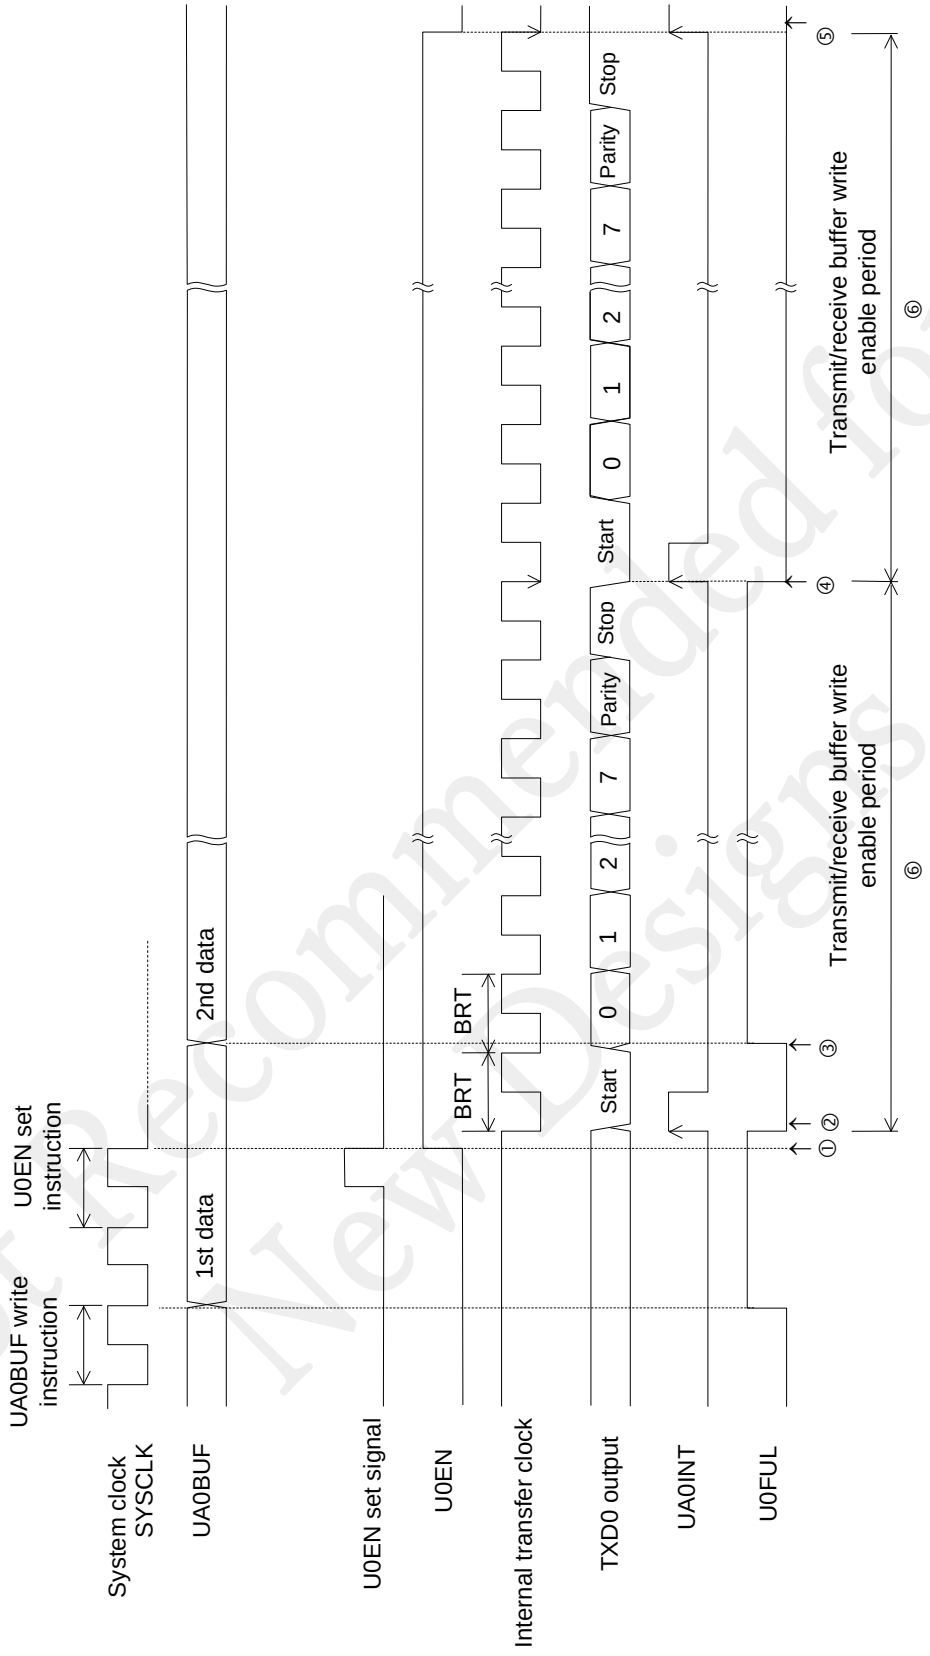

Figure 14-5 Operation Timing in Transmission

14.3.5 Receive Operation

Reception is started by selecting a receive data input pin using the U0RSEL bit of the UART0 mode register 0 (UA0MOD0), then setting the U0IO bit of UA0MOD0 to "0" to select receive mode, and then setting the U0EN bit of the UART0 control register (UA0CON) to "1".
Figure 14-6 shows the operation timing for reception.

When receive operation starts, the LSI checks the data sent to the input pin RXD0 and waits for the arrival of a start bit. When detecting a start bit (②), the LSI generates the internal transfer clock of the baud rate set with the start bit detect point as a reference and performs receive operation.
The shift register shifts in the data input to RXD on the rising edge of the internal transfer clock. The data and parity bit are shifted into the shift register and 5- to 8- bit receive data is transferred to the transmit/receive buffer (UA0BUF) concurrently with the fall of the internal transfer clock of ③.
The LSI requests a UART0 interrupt on the rising edge of the internal transfer clock subsequent to the internal transfer clock by which the receive data was fetched (④) and checks for a stop bit error and a parity bit error. When an error is detected, the LSI sets the corresponding bit of the UART0 status register (UA0STAT) to "1".

Parity error : S0PER = "1"
Overrun error : S0OER = "1"
Framing error : S0FER = "1"

As shown in Figure 14-6, the rise of the internal transfer clock is set so that it may fall into the middle of the bit interval of the receive data.
Reception continues until the U0EN bit is reset to "0" by the program. When the U0EN bit is reset to "0" during reception, the data received may be destroyed. When the U0EN bit is reset to "0" during the "U0EN reset enable period" in Figure 14.6, the data received is protected.

15.3 Description of Operation

15.3.1 Communication Operating Mode

Communication is started when communication mode is selected by using the I^2C bus 0 mode register (I2C0MOD), the I^2C function is enabled by using the I20EN bit, a slave address and a data communication direction are set in the I^2C bus 0 slave address register, and "1" is written to the I20ST bit of the I2C bus 0 control register (I2C0CON).

15.3.1.1 Start Condition

When "1" is written to the I20ST bit of the I^2C bus 0 control register ((I2C0CON) while communication is stopped (the I20ST bit is "0"), communication is started and the start condition waveform is output to the SDA and SCL pins.
After execution of the start condition, the LSI shifts to slave address transmit mode.

15.3.1.2 Repeated Start Condition

When "1" is written to the I20RS and I20ST bits of the I^2C bus 0 control register ((I2C0CON) during communication (the I20ST bit is "1"), the repeated start condition waveform is output to the SDA and SCL pins. If the communication is still wished on the bus, it can generate a repeated START condition, address another slave and reverse the transmit/receive without first generating a STOP condition (see Figure 15-4 Operation Timing at Data Transmit/Receive Mode (Write/Read) Switching).
After execution of the repeated start condition, the LSI shifts to slave address transmit mode.

15.3.1.3 Slave Address Transmit Mode

In slave address transmit mode, the values (slave address and data communication direction) of the I^2C bus 0 slave address register (I2C0SA) are transmitted in MSB first, and finally, the acknowledgment signal is received in the I20ACR bit of the I^2C bus 0 status register (I2CSTAT). I20ACR bit becomes "0" after acknowledgement "0" is received and I20ACR bit becomes "1" after acknowledgement "1" is received.
At completion of acknowledgment reception, the LSI shifts to the I^2C bus 0 control register (I2C0CON) setting wait state (control register setting wait state).
The value of I2C0SA output from the SDA pin is stored in I2C0RD when the LSI shifts to the I^2C bus 0 control register (I2C0CON) setting wait state (control register setting wait state).

15.3.1.4 Data Transmit Mode

In data transmit mode, the value of I2C0TD is transmitted in MSB first, and finally, the acknowledgment signal is received in the I20ACR bit of the I^2C bus 0 status register (I2CSTAT). I20ACR bit becomes "0" after acknowledgement "0" is received and I20ACR bit becomes "1" after acknowledgement "1" is received.
At completion of acknowledgment reception, the LSI shifts to the I^2C bus 0 control register (I2C0CON) setting wait state (control register setting wait state).
The value of I2C0TD output from the SDA pin is stored in I2C0RD.

15.3.1.5 Data Receive Mode

In data receive mode, the value input in the SDA pin is received synchronously with the rising edge of the serial clock output to the SCL pin, and finally, the value of the I20ACT bit of the I2C bus 0 control register (I2C0CON) is output as a acknowledgement. For example, as shown on Figure 15-3 and Figure 15-4, after I20ACT bit is set to "0" (I2CON = "01H"), acknowledgement "0" ("A" acknowledgement transfer on the Figures) is output And after I20ACT bit is set to "1" (I2CON = "81H"), acknowledgement "1" ("A" non-acknowledgement transfer on the Figures) is output.
At completion of acknowledgment transmission, the LSI shifts to the I^2C bus 0 control register (I2C0CON) setting wait state (control register setting wait state).
The data received is stored in I2C0RD after the acknowledgment signal is output. The acknowledgment signal output is received in the I20ACR bit of the I^2C bus 0 status register (I2CSTAT).

15.3.1.6 Control Register Setting Wait State

When the LSI shifts to the control register setting wait state, an I^2C bus interface interrupt (I2C0INT) is generated.
In the control register setting wait state, the transmit flag (I20ER) of the I^2C bus 0 status register (I2C0STAT) and acknowledgment receive data (I20ACR) are confirmed and at data reception, the contents of I2C0RD are read in the CPU and the next operation mode is selected.

When "1" is written to the I20ST bit in the control register setting wait state, the LSI shifts to the data transmit or receive mode. When "1" is written to the I20SP bit, the LSI shifts to the stop condition. When "1" is written to the I20RS bit and I2ST bit, the operation shifts to the repeated start condition.

15.3.1.7 Stop Condition

In the stop condition, the stop condition waveform is output to the SDA and SCL pins. After the stop condition waveform is output, an I^2C bus interface interrupt (I2C0INT) is generated.

15.3.2 Communication Operation Timing

Figures 15-2 to 15-4 show the operation timing and control method for each communication mode.

When the values of the transmitted bit and the SDA pin do not coincide, the I20ER bit of the I2C bus 0 status register (I2C0STAT) is set to "1" and SDA pin remains the output until termination of the subsequent byte data communication. I20ERR bit is initialized to "0" by writing I²C Bus 0 Control Register (I2C0COCON).

The level of the NMI pin can be read by reading the NMI data register (MMID).

16.3.1 Interrupt Request

When a level change occurs at the NMI pin after the duration longer than the minimum NMI interrupt pulse width, a non-maskable interrupt which does not depend on the master interrupt enable flag (MIE) is generated.
Figure 16-2 shows the NMI interrupt generation timing.

17.3 Description of Operation

For each pin of Port 0, the setting of the Port 0 control registers 0 and 1 (P0CON0 and P0CON1) allows selection of high-impedance input mode, input mode with a pull-down resistor, or input mode with a pull-up resistor. High-impedance input mode is selected at system reset.

The Port 0 pins (P00, P01, P02, P03) can be used for P00 to P03 interrupts (P00INT to P03INT). The P00 to P03 interrupts are maskable and interrupt enable or disable can be selected. For details of interrupts, see Chapter 5, "Interrupts".
The P00 and P01 pins can be used as the trigger input for the capture circuit and the P02 pin can be used as the RXD0 input pin of UART0.
For the capture function and the UART function, see Chapter 8, "Capture," and Chapter 14, "UART," respectively.

18.3 Description of Operation

18.3.1 Input Port Function

For each pin of Port 1, one of high-impedance input mode, input mode with a pull-down resistor, and input mode with a pull-up resistor can be selected by setting the Port 1 control registers 0 and 1 (P1CON0 and P1CON1). At system reset, high-impedance input mode is selected as the initial state.

An external clock input pin is assigned to Port 1 as a secondary function. Supply the clock to P10 pin and select the external clock input mode by setting the OSCM0 bit of frequency control register 0 (FCON0) to "1".

Note:
No port mode register is provided for switching between the primary function and the secondary function of Port 1. When using the Port 1 pins as the external clock input, pin mode is switched according to the values set in the OSCM0 bit of the FCON0 register.
See Chapter 6, "Clock Generation Circuit," for the details of the FCON0 register and the external clock input.

19.3 Description of Operation

19.3.1 Output Port Function

For each pin of Port 2, any one of high-impedance output mode, P-channel open drain output mode, N-channel open drain output mode, and CMOS output mode can be selected by setting the Port 2 control registers 0 and 1 (P2CON0 and P2CON1). At a system reset, high-impedance output mode is selected as the initial state.
Depending of the value set in the Port 2 data register (P2D), a "L" level or "H" level signal is output to each pin of Port 2.

19.3.2 Secondary Function

Low-speed clock (LSCLK) output, High-speed output clock (OUTCLK) output, or buzzer 0 (MD0) output is assigned to Port 2 as a secondary function. The secondary function can be used by setting the P22MD to P20MD bits of the Port 2 mode register (P2MOD) to "1".

For clock output and buzzer 0 (BZ0) output, see Chapter 6, "Clock Generation Circuit" and Chapter 23, "Buzzer", respectively.

20.3 Description of Operation

20.3.1 Input/Output Port Functions

For each pin of Port 3, either output or input is selected by setting the Port 3 direction register (P3DIR).
In output mode, high-impedance output mode, P-channel open drain output mode, N-channel open drain output mode, or CMOS output mode can be selected by setting the Port 3 control registers 0 and 1 (P3CON0 and P3CON1).
In input mode, high-impedance input mode, input mode with a pull-down resistor, or input mode with a pull-up resistor can be selected by setting the Port 3 control registers 0 and 1 (P3CON0 and P3CON1).
At a system reset, high-impedance output mode is selected as the initial state.
In output mode, "L" or "H" level is output to each pin of Port 3 depending on the value set by the Port 3 data register (P3D).
In input mode, the input level of each pin of Port 3 can be read from the Port 3 data register (P3D).

20.3.2 Secondary and Tertiary Functions

Secondary and tertiary functions are assigned to Port 3 as the RC-ADC (channel 0) oscillation pins (IN0, CS0, RS0, RT0, RCT0, RCM) and the PWM output pin (PWM0). These pins can be used in a secondary or tertiary function mode by setting the P35MD0 to P30MD0 bits and the P35MD1 to P30MD1 bits of the Port 3 mode registers (P3MOD0, P3MOD1). For RC-ADC and PWM, see Chapter 24, "RC Oscillation Type A/D converter", and Chapter 11, "PWM".

Note:
All the port 3 pins except P35/RCM are configured as pins dedicated to the RC-ADC function during A/D conversion. Therefore, if there is any unused pin, that pin cannot be used as its primary function during A/D conversion. For the RC-ADC, see Chapter 24, "RC Oscillation Type A/D Converter".

21.3 Description of Operation

21.3.1 Input/Output Port Functions

For each pin of Port 4, either output or input is selected by setting the Port 4 direction register (P4DIR).
In output mode, high-impedance output mode, P-channel open drain output mode, N-channel open drain output mode, or CMOS output mode can be selected by setting the Port 4 control registers 0 and 1 (P4CON0 and P4CON1).
In input mode, high-impedance input mode, input mode with a pull-down resistor, or input mode with a pull-up resistor can be selected by setting the Port 4 control registers 0 and 1 (P4CON0 and P4CON1).
At a system reset, high-impedance output mode is selected as the initial state.
In output mode, "L" or "H" level is output to each pin of Port 4 depending on the value set by the Port 4 data register (P4D).
In input mode, the input level of each pin of Port 4 can be read from the Port 4 data register (P4D).

21.3.2 Secondary and Tertiary Functions

Secondary and tertiary functions are assigned to Port 4 as the I2C bus 0 pins (SDA, SCL), UART 0 pins (RXD0, TXD0), RC-ADC (channel 1) oscillation pins (IN1, CS1, RS1, RT1), synchronous serial port 0 pins (SIN0, SCK0, SOUT), and the PWM output pin (PWM0). These pins can be used in a secondary or tertiary function mode by setting the P47MD0 to P40MD0 bits and the P47MD1 to P40MD1 bits of the Port 4 mode registers (P4MOD0, P4MOD1).
See the following chapters for reference:

I2C bus:	Chapter 15 "I2C Bus Interface"
UART:	Chapter 14 "UART"
RC-ADC:	Chapter 24 "RC Oscillation Type A/D Converter"

Note:
The P44 to P47 pins of port 4 are configured as pins dedicated to the RC-ADC function during A/D conversion. Therefore, if there is any unused pin, that pin cannot be used during A/D conversion. For the RC-ADC, see Chapter 24, "RC Oscillation Type A/D Converter".

22.3 Description of Operation

22.3.1 Input/Output Port Functions

For each pin of Port A, either output or input is selected by setting the Port A direction register (PADIR).
In output mode, high-impedance output mode, P-channel open drain output mode, N-channel open drain output mode, or CMOS output mode can be selected by setting the Port A control registers 0 and 1 (PACON0 and PACON1).
In input mode, high-impedance input mode, input mode with a pull-down resistor, or input mode with a pull-up resistor can be selected by setting the Port A control registers 0 and 1 (PACON0 and PACON1).
At system reset, high-impedance output mode is selected as the initial state.
In output mode, "L" or "H" level is output to each pin of Port A depending on the value set by the Port A data register (PAD).
In input mode, the input level of each pin of Port A can be read from the Port A data register (PAD).

RC Oscillation Type A/D Converter

24. RC Oscillation Type A/D Converter

24.1 Overview

This LSI has a built-in 2-channel RC oscillation type A/D converter (RC-ADC).
The RC-ADC converts resistance values or capacitance values to digital values by counting the oscillator clock whose frequency changes according to the resistor or capacitor connected to the RC oscillator circuits. By using a thermistor or humidity sensor as a resistor, a thermometer or hygrometer can be formed.
In addition, a different sensor for each of the two channels of RC-ADC's RC oscillator circuit can be used to broaden RC-ADC applications; for example, the conveter can be used for expansion of measurement range or measurement at two points.
For input clock, see Chapter 6, "Clock Generation Circuit."

[Description of Bits]

- **RARUN** (bit 0)
  The RARUN bit is used to start A/D conversion of the RC-ADC. When RARUN is set to "1", A/D conversion starts. If Counter A or Counter B overflows with RARUN set to "1", the bit is automatically reset to "0".
  RARUN is set to "0" at system reset.

RARUN	Description
0	Stops A/D conversion (initial value).
1	Starts A/D conversion.

Note:
When A/D conversion is stopped by resetting the RARUN to "0", the RC-ADC does not perform properly without the following procedures.

1) Set the "DRAD" bit of the Block Control Register 4 (BLKCON4) to "1" , in order to disable the RC-ADC.
2) Reset the "DRAD" bit of the Block Control Register 4 (BLKCON4) to "0" , in order to enable the RC-ADC.
3) Set up the RC-ADC again by following the required procedures, then restart.

24.3 Description of Operation

Counter A (RADCA0–2) is a 24-bit binary counter for counting the base clock (BSCLK), which is used as the standard of time. Counter A can count up to 0FFFFFFH.
Counter B (RADCB0–2) is a 24-bit binary counter for counting the oscillator clock (RCCLK) of the RC oscillator circuits. Counter B can count up to 0FFFFFFH.
Counters A and B are provided with overflow flags (OVFA and OVFB, respectively). Each overflow output results in generation of an RC-ADC interrupt request signal (RADINT). Use the RADI bit of the RC-AC mode register (RADMOD) to select whether to generate an overflow interrupt by an overflow on Counter A or Counter B: setting RADI to "0" specifies Counter A overflow and setting it to "1" specifies Counter B overflow.

The RARUN bit of the RC-AD control register (RADCON) is used to start or stop RC-ADC conversion operation. When RARUN is set to "0", the oscillator circuits stop, so that counting will not be performed. When RARUN is set to "1", RC oscillation starts, when the RC oscillator clock (RCCLK) and the base clock (BSCLK) start counting through Counter B and Counter A.

The RC oscillation section has a total of eight types of oscillation modes based on the two oscillator circuits of RCOSC0 and RCOSC1, and mode selection is made by the RC-ADC mode register (RADMOD).
P30–34, P44–47, and P35 must be configured as their secondary function input or output when using 1) the RC oscillator circuit RCOSC0, 2) the RC oscillator circuit RCOSC1, and 3) the RC monitor pin (RCM) that outputs RC oscillation waveforms, respectively. For the configuration of the RC oscillator circuits, see Section 24.1.2, "Configuration"; for the secondary functions of Port 3, see Chapter 20, "Port 3"; for the secondary functions of Port 4, see Chapter 21, "Port 4".

24.3.1 RC Oscillator Circuits

RC-ADC performs A/D conversion by converting the oscillation frequency ratio between a reference resistor (or capacitor) and a resistive sensor (or capacitive sensor) such as a thermistor to digital data.
By making RC oscillation occur both on the reference side and on the sensor side with the reference capacitor the error factor that the RS oscillator circuit itself is eliminated, thereby making it possible to perform the A/D conversion of the characteristics of the sensor itself.
Also, by calculating the ratio between the oscillation frequency on the reference side and that on the sensor side and then calculating the correlation between the calculated ratio and temperatures that the sensor characteristics have in advance, a temperature can be obtained based on that calculated ratio.
Table 24-1 lists the eight types of oscillation modes, one of which is selected by the RC-ADC mode register (RADMOD) OM3–0 bits.

(Setting prohibited) : The oscillator clock is not supplied even by setting the RARUN bit to "1" or by starting A/D conversion.

In Table 24-1, mode No.0 and mode No.7 are modes where external clocks to be input to the IN0 or IN1 pin are used for measurement with the RC oscillator circuit stopped.
As shown in Table 24-1, the two oscillator circuits, RCOSC0 and RCOSC1, are so specified that they cannot operate concurrenty in order to prevent interference in oscillation from occurring when they oscillate concurrently.
The relationship between an oscillation frequency f_{RCCLK} and an RC constant is expressed by the following equation:

$$\frac{1}{f_{RCCLK}} = t_{RCCLK} = k_{RCCLK} \cdot R \cdot C$$

where t_{RCCLK} is the period of the oscillator clock, k_{RCCLK} the proportional constant, and R･C the product of capacitances CS, CT, (CS+CVR) and （CT＋CVR） and resistances RS and RT. CS, CT, (CS+CVR), (CT+CVR), RS, and RT concern oscillation. The value of k_{RCCLK} slightly changes depending on the value of the supply voltage VDD, RI, R, or C.
Table 24-2 lists the typical k_{RCCLK} values.

Notes:
- Out of the Port 3 and Port 4 pins, pins that are to be used for the RC-ADC function must be configured as secondary function input or output using the mode register (P3MOD0, P3MOD1, P4MOD0, P4MOD1) of the corresponding port.
- All the Port 3 pins except P35/RCM (see Section 24.1.3, "List of Pins") are configured as pins dedicated to the RC-ADC function during A/D conversion. Therefore, during A/D conversion, all the Port 3 pins except P35 cannot be used as their primary functions in oscillation mode No. 0, 1, 2, 3 or 4, which is selected by the RADMOD register. In the same way, the P44 to P47 pins of Port 4 cannot be used as their primary functions in oscillation mode No. 5, 6 or 7.

24.3.2 Counter A/Counter B Reference Modes

There are the following two modes of RC-ADC conversion operation:

- Counter A reference mode (RADMOD RADI = "0")
  In this mode, a gate time is determined by Counter A and the base clock (BSCLK), which is used as the time reference, then the RC oscillator clock (RCCLK) is counted by Counter B within the gate time to make the content of Counter B an A/D conversion value.
  The A/D conversion value is proportional to RC oscillation frequency.

- Counter B reference mode (RADMOD RADI = "1")
  In this mode, a gate time is determined by Counter B and the RC oscillator clock (RCCLK), and the base clock (BSCLK), which is used as the time reference, is counted by Counter A within the gate time to make the content of Counter A an A/D conversion value.
  The /D conversion value is inversely proportional to RC oscillation frequency.

(1) Operation in Counter A reference mode

Figure 24-6 shows the operation timing in Counter A reference mode.
Following is an example of operation procedure in Counter A reference mode:

① Preset to Counter A (RADCA2–0) the value obtained by subtracting the count value "nA0" from the maximum value + 1 (1000000H). The product of the count value "nA0" and the BSCLK clock period indicates the gate time.
② Preset "000000H" to Counter B (RADCB2–0).
③ Set the OM3–OM0 bits of RADMOD to desired oscillation mode (see Table 16-1).
④ Set the RADI bit of RADMOD to "0" to specify generating of an interrupt request signal by Counter A overflow.
⑤ Set the RARUN bit of RADCON to "1" to start A/D conversion.

Counter A starts counting of the base clock (BSCLK) when RARUN is set to "1" and the RCON signal (signal synchronized with the fall of the base clock) is set to "1". When Counter A overflows, the RARUN bit is automatically reset to "0" (⑥) and counting is terminated. At the same time, an RC-ADC interrupt request (RADIN) occurs (⑦).

When the RCON signal is set to "1", the RC oscillator circuit starts operation and Counter B starts counting of the RC oscillator clock (RCCLK). When the RARUN bit is reset to "0" due to overflow of Counter A, RC oscillation stops and Counter B stops counting.
The final count value "nB0" of Counter B is the RCCLK count value during the gate time "$nA0 \cdot t_{BSCLK}$" and is expressed by the following expression:

$$nB0 \quad \cong \quad nA0 \cdot \frac{t_{BSCLK}}{t_{RCCLK}} \quad \propto \quad f_{RCCLK}$$

where t_{BSCLK} indicates the BSCLK period and t_{RCCLK} the RCCLK period. That is, "nB0" is a value proportional to the RC oscillation frequency f_{RCCLK}.

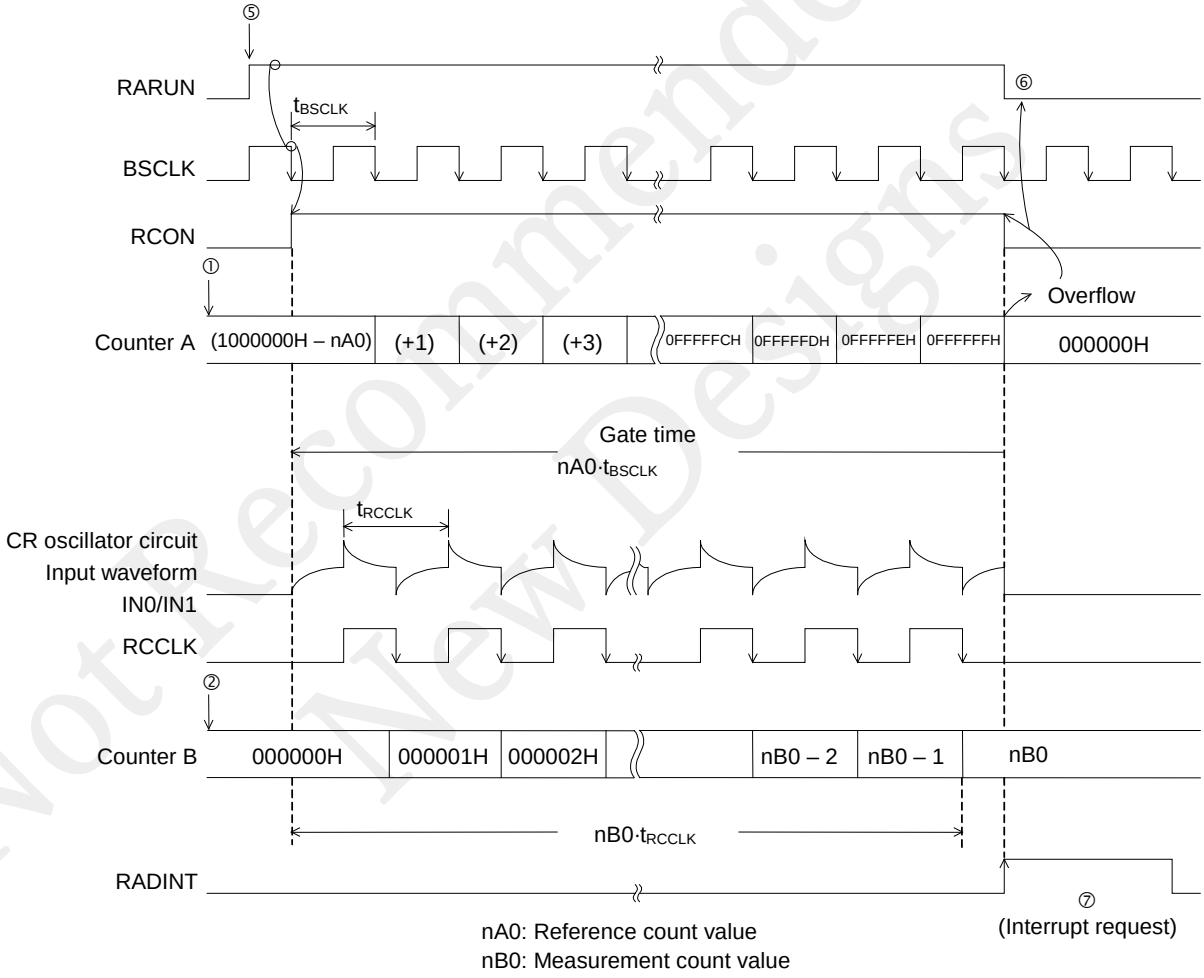

Figure 24-6 Operation Timing in Counter A Reference Mode

(2) Operation in Counter B reference mode

Figure 24-7 shows the operation timing in Counter B reference mode.
Following is an example of operation procedure in Counter B reference mode:

① Preset to Counter B (RADCB2–0) the value obtained by subtracting the count value "nB1" from the maximum value + 1 (1000000H). The product of the count value "nB1" and the RCCLKclock period indicates the gate time.
② Preset "000000H" to Counter A (RADCA2–0).
③ Set the OM3–OM0 bits of RADMOD to desired oscillation mode (see Table 16-1).
④ Set the RADI bit of RADMOD to "1" to specify generating of an interrupt request signal by Counter B overflow.
⑤ Set the RARUN bit of RADCON to "1" to start A/D conversion.

When the RARUN bit is set to "1" and the RCON signal (signal synchronized with the fall of the base clock) is set to"1", the RC oscillator circuit starts operation and Counter B starts counting of the RC oscillator clock (RCCLK). When Counter B overflows, the RARUN bit is automatically reset (⑥) and conversion operation terminates. At the same time, an RC-ADC interrupt request (RADINT) occurs. (⑦)

When the RCON signal is set to "1", Counter A starts counting of the base clock (BSCLK). When the RARUN bit is reset due to overflow of Counter B, Counter A stops counting.
The final count "nA1" of Counter A is the CLK count value during the gate time "$nB1 \cdot t_{RCCLK}$" and is expressed by the following expression:

$$nA1 \quad \cong \quad nB1 \cdot \frac{t_{RCCLK}}{t_{BSCLK}} \propto \frac{1}{f_{RCCLK}}$$

That is, "nA1" is a value inversely proportional to the RC oscillation frequency f_{RCCLK}.

24.3.3 Example of Use of RC Oscillation Type A/D Converter

This section describes the method of performing A/D conversion for sensor values in Counter A and B reference modes by taking temperature measurement by a thermistor as an example.
Figure 24-8 shows the configuration of 1-thermistor RC oscillator circuit using RCOSC0.

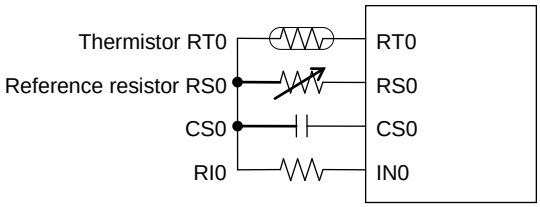

Figure 24-8 Configuration of 1-Thermistor RC Oscillator Circuit Using RCOSC0

Figure 24-9 shows the temperature characteristics of the thermistor resistance RT0.

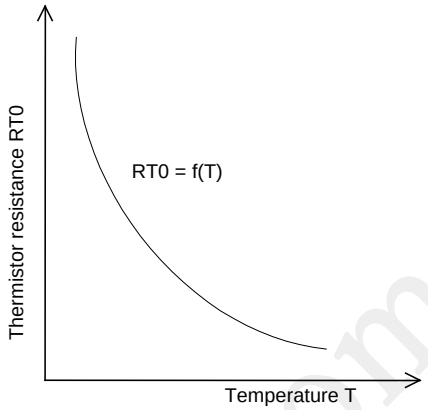

Figure 24-9 Temperature Characteristics of Thermistor

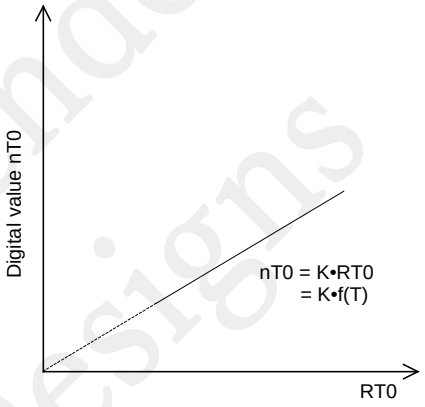

Figure 24-10 A/D Conversion Characteristics (Ideal characteristics when nT0 is proportional to RT0)

RT0 is expressed as a function of temperature T by the following equation:

$$RT0 = f(T)$$

Figure 24-10 shows the ideal characteristics of A/D conversion with the assumption that RT0 is an analog quantity. In the ideal characteristics, the A/D conversion value nT0 will purely depend on RT0 only. Assuming that nT0 is proportional to RT0, let proportional constant be K, then nT0 has the following relationship with temperature T:

$$nT0 = K \cdot RT0 = K \cdot f(T) \quad \ldots\ldots \text{Expression A}$$

Therefore, temperature T can be expressed as a digital value by performing the conversion processing that accords with the characteristics shown in Figure 24-9 for nT0 by software.

To convert from an RT0 value to a digital value, the ratio is used between a) the oscillation frequency by the thermistor connected to the RT0 pin and the capacitor connected to the CS0 pin and b) the oscillation frequency by the reference resistor (which ideally should have no temperature characteristics) connected to the RS0 pin and the capacitor connected to the CS0 pin. This is for making the conditions other than resistance equal to eliminate the error factor in oscillation characteristics.
As shown in Figures 24-9 and 24-11, the RT0 value depends on temperature T and the RS0 value is assumed to be constant regardless of temperature T. It is ideal if the characteristics of the oscillation frequency fOSC to temperature T using these resistances will be like the solid lines in Figures 24-12 and 24-13; however, in reality, it would appear that they will be like the dotted lines due to error factors such as IC temperature characteristics.
Since the condition of f_{RCCLK} (RT0) and that of f_{RCCLK} (RS0) are the same except for the resistances, the error ratios are almost the same; therefore, errors can almost be eliminated by using the ratio between f_{RCCLK} (RT0) and f_{RCCLK} (RS0).
The ratio between f_{RCCLK} (RT0) and f_{RCCLK} (RS0) is equivalent to the above-mentioned A/D conversion value nT0 that should ideally depend only on RT0.

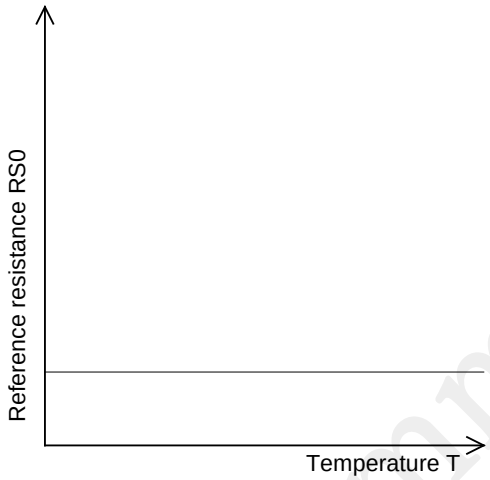

Figure 24-11 Temperature Characteristics of Reference Resistor

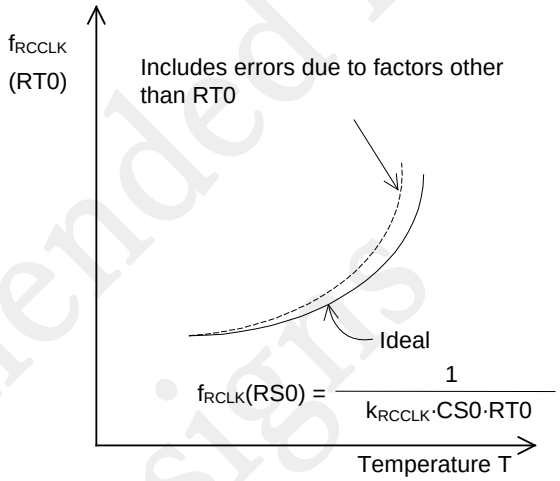

Figure 24-12 Oscillation Characteristics of Thermistor

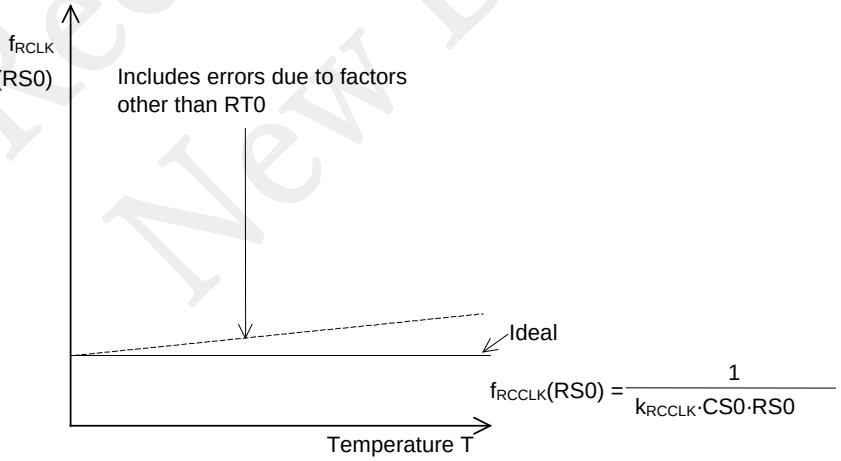

Figure 24-13 Oscillation Characteristics of Reference Resistor

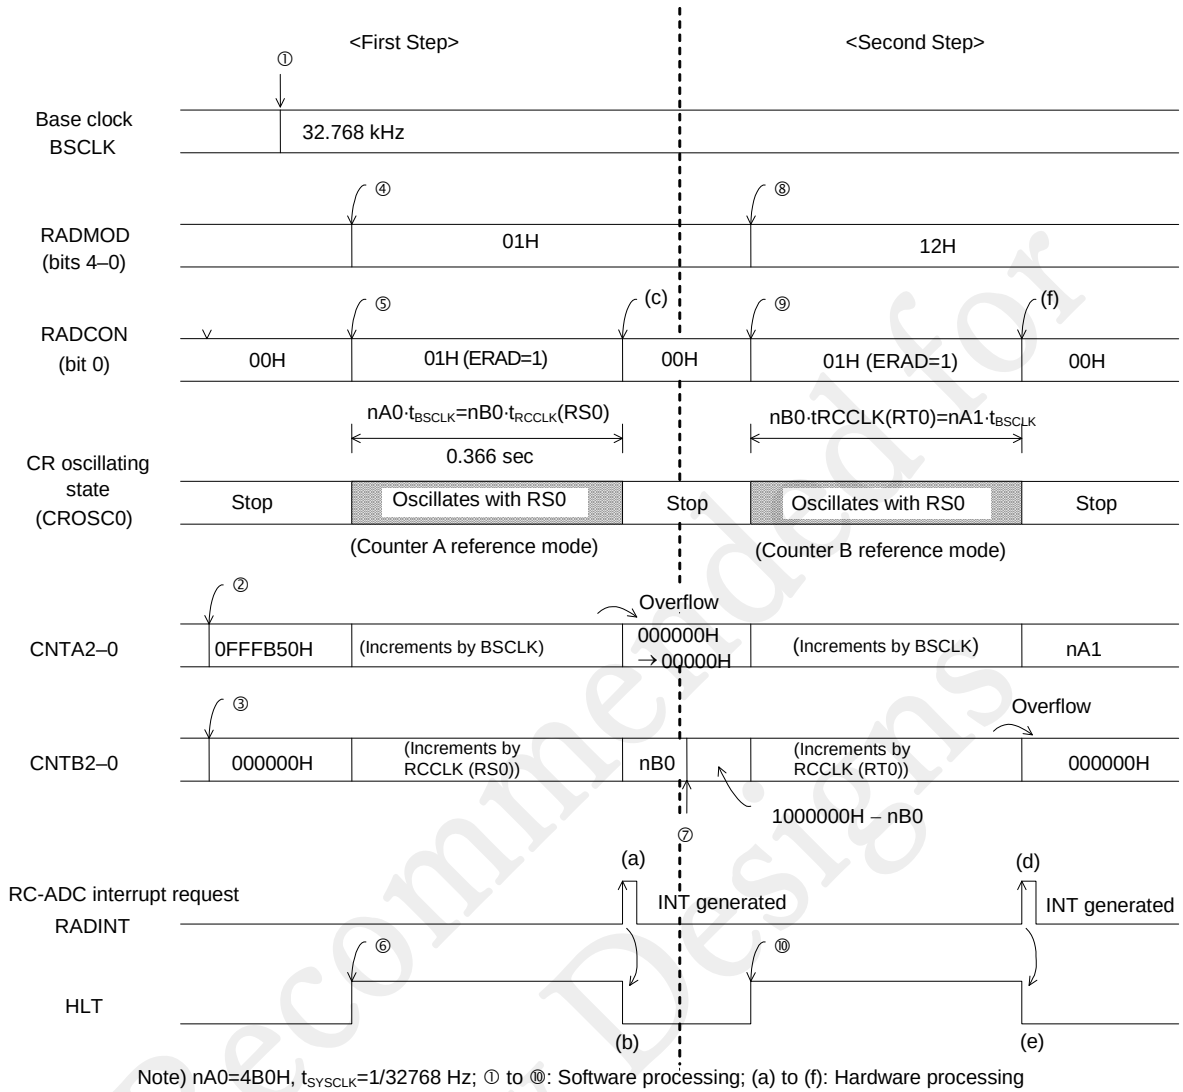
Figure 24-14 shows, as an example of method, a timing diagram of one cycle of conversion from analog value RT0 to a digital value, that is, A/D conversion.
Basically, one A/D conversion cycle must consist of two steps, as shown in Figure 24-14. The reason for requiring two steps is that the reference resistor and the thermistor must first be oscillated separately and then the ratio between the oscillation frequencies of them is used, as described above.
In the example below, operation for these two steps is performed using the following combination:

- First step = RC oscillation with RS0 in Counter A reference mode
- Second step = RC oscillation with RT0 in Counter B reference mode

Besides this, there would be several possible A/D conversion methods.
In the above method, the operation time (gate time) for the second step fluctuates depending on the value of thermistor RT0. To avoid the fluctuation of the operation time, using a method that uses the following combination is recommended:

- First step = RC oscillation with RS0 in Counter B reference mode
- Second step = RC oscillation with RT0 in Counter A reference mode

A/D conversion procedure is explained below by taking Figure 24-14 as an example.



Note) nA0=4B0H, t_{SYSCLK}=1/32768 Hz; ① to ⑩: Software processing; (a) to (f): Hardware processing

Figure 24-14 Timing Diagram for 1 Cycle of A/D Conversion (Example)

<First Step>

① Set the base clock to 32.768 kHz. (Write "00H" in FCON0.)
② Preset "1000000H – nA0" in Counter A.
③ Preset "000000H" in Counter B.
④ Write "01H" in RADMOD to select Counter A reference mode and the oscillation mode that uses reference resistance RS0.
⑤ Write "01H" in RADCON to start A/D conversion operation.
⑥ Write "1" in the HLT bit of SBYCON (see Chapter 4, "MCU") to set the device to HALT mode.

Note:
In this example, nA0 is set to 4B0H because the gate time "$nA0 \cdot t_{BSCLK}$" in oscillation mode with reference resistor RS0 is set to 0.3666 second(in the case of ML610Q411/Q412). The value of nA0 is related to how much the margin of the quantizatoin error of the A/D conversion is: the greater the nA0 value is, the smaller the margin of error becomes.
To reduce noise contamination to the RC oscillator circuit caused by CPU operation, it is recommended to constantly put the device into HALT mode during operation of RC oscillation.

From this point of time, the RC oscillator circuit (RCOSC0) continues oscillation for about 0.366 second with the reference resistance RS0. Then, when Counter A overflows, the RADINT signal is set to "1" and an RC-ADC interrupt request is generated (section (a)). Also, the generation of interrupt request releases HALT mode (section (b)) and at the same time, A/D conversion operation stops (section (c), RARUN bit = "0"). At this time, Counter A is set to "000000H".
The content of Counter B at this time is expressed by the following expression:

$$nB0 = nA0 \cdot \frac{t_{BSCLK}}{t_{RCCLK}(RS0)} \quad \text{…… Expression B}$$

That completes the operations in First Step .

<Second Step>

⑦ Calculate "1000000H – nB0" from the content of Counter B "nB0" and set the obtained value in Counter B. At this point, Counter A needs to be cleared; however, no processing is required since the counter is already set to "000000H".
⑧ Write "12H" in RADMOD to select Counter B reference mode and the oscillation mode that uses thermistor RT0.
⑨ Write "01H" in RADCON to start A/D conversion operation.
⑩ Write "1" in the HLT bit of SBYCON (see Chapter 4, "MCU") to set the device to HALT mode.

The RC oscillator circuit (RCOSC0) oscillates with thermistor RT0 from this point until Counter B overflows. This period is equal to the product of "nB0" obtained in the First Step and the oscillation period t_{RCCLK} (RT0) using RT0.
When Counter B overflows, the RADINT signal is set to "1" and an RC-ADC interrupt request is generated (section (d)). Also, the generation of interrupt request releases HALT mode (section (e)) and at the same time, A/D conversion operation stops (section (f), RARUN bit = "0").
This completes the operations in Second Step .

The content of Counter A at this time becomes the A/D converison value nA1, which is expressed by the following expression:

$$nA1 = nB0 \cdot \frac{t_{RCCLK}\ (RT0)}{t_{BSCLK}} \quad \text{…… Expression C}$$

From expressions B and C, nA1 is expressed by the following expression:

$$nA1 = nA0 \cdot \frac{t_{RCCLK}\ (RT0)}{t_{RCCLK}\ (RS0)} \quad \text{…… Expression D}$$

where t_{RCCLK} (RS0) is the oscillator clock period by reference resistor RS0 and t_{RCCLK} (RT0) the oscillator clock period by thermistor RT0.
Since the oscillation period is expressed by "$t_{RCCLK} = k_{RCCLK} \cdot R \cdot C$", t_{RCCLK} (RS0) and t_{RCCLK} (RT0) are expressed by the following expressions:

$$t_{RCCLK}(RS0) = k_{RCCLK} \cdot (CS0+CVR) \cdot RS0$$
$$t_{RCCLK}(RT0) = k_{RCCLK} \cdot (CS0+CVR) \cdot RT0 \quad \ldots\ldots \text{Expression E}$$

When expression E is substituted for expression D, nA1 will be:

$$nA1 = nA0 \cdot \frac{RT0}{RS0}$$

Since "nA0" ("4B0H" in this example) and RS0 are constants whose values are fixed, "nA1" is a digital value proportional to RT0. This very "nA1" corresponds to "nT0" in expression A.

That concludes the description of the A/D conversion method using a thermistor. "nA1" that has been obtained must further be converted to a value such as a temperature indication value for thermometer by program according to the temperature-to-resistance characteristics of the themistor.

24.3.4 Monitoring RC Oscillation

The RC oscillator clock (RCCLK) can be output using the secondary function of the P35 pin of Port 3. See Chapter 20, "Port 3," for the details of the secondary function of P35.
Monitoring RC oscillation is useful for checking the characteristics of the RC oscillator circuit. That is, the relationship between a sensor, such as a thermistor, and the oscillation frequency can be measured. For instance, the coefficient for conversion from the above-described nA1 value to a temperature indication value can be obtained by checking the relationship between the ambient temperature of a themistor-incorporated RC oscillator, the oscillation frequency with thermistor RT0, and the oscillation frequency with reference resistor RS0.

Note:
- P35 (RCM) is a monitor pin for oscillation clock. The channel 0(P34-P30) and channel 1(P47-P44) share the monitor pin.
- Please use P35 (RCM) for the evaluation purpose and disable the output while operating in an actual application to minimize the noise.

Initial value: 02H

SADCON0	—	—	—	—	—	—	—	SALP
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

SADCON0 is a special function register (SFR) used to control the operation of the SA-ADC.

[Description of Bits]

- **SALP** (bit 0)

SALP	Description
0	Single A/D conversion only (Initial value)
1	Consecutive A/D conversion

This bit is used to select whether A/D conversion is performed once only for each channel or consecutively. When this bit is set to "0", A/D conversion is performed once only for each channel and when it is set to "1", A/D conversion is performed consecutively according to the settings of the SA-ADC mode register (SADMOD0).

Notes:
Set the SALP bit when the SARUN bit of the SADCON1 register is "0" (A/D conversion inactive).
Use the SADMOD0 register to select a channel. See Section 25.3.2, A/D Conversion Channel Settings, for the details.

25.2.7 SA-ADC Control Register 1 (SADCON1)

Address: 0F2F1H
Access: R/W
Access size: 8 bits
Initial value: 00H

	7	6	5	4	3	2	1	0
SADCON1	—	—	—	—	—	—	—	SARUN
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

SADCON1 is a special function register (SFR) used to control the operation of the SA-ADC.

[Description of Bits]

- **SARUN** (bit 0)

SARUN	Description
0	Stops conversion. (Initial value)
1	Starts conversion.

The SARUN bit is used to start or stop SA-ADC conversion. Setting this bit to "1" starts A/D conversion and setting it to "0" stops A/D conversion.
When SALP of SADCON0 is "0" and then A/D conversion on the channel with the largest channel number among the selected ones is terminated, the SARUN bit is automatically set to "0".

Notes:
Do not start A/D conversion in the state in which bits 1 (SACH1) and 0 (SACH0) of SA-ADC mode register 0 are "0" and "0" respectively. When A/D conversion is started in this state, A/D conversion is not done while the A/D converter is activated. Therefore, the SA-ADC result register is not updated, the A/D conversion termination interrupt is not generated, A/D conversion is not terminated automatically, and SARUN remains "1".

25.2.8 SA-ADC Mode Register 0 (SADMOD0)

Address: 0F2F2H
Access: R/W
Access size: 8 bits
Initial value: 00H

	7	6	5	4	3	2	1	0
SADMOD0	—	—	—	—	—	—	SACH1	SACH0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

SADMOD0 is a special function register (SFR) used to choose A/D conversion channel(s).

[Description of Bits]

- **SACH0** (bit 0)

SACH0	Description
0	Stops conversion on channel 0. (Initial value)
1	Performs conversion on channel 0.

- **SACH1** (bit 1)

SACH1	Description
0	Stops conversion on channel 1. (Initial value)
1	Performs conversion on channel 1.

The SACH1 and SACH0 bits are used to select channel(s) on which A/D conversion is performed. If both channel 1 and channel 0 are set to "1", A/D conversion is performed on channel 0 first, and then channel 1.

Do not start A/D conversion both channel 1 and channel 0 set to 0. If conversion is started, the A/D conversion circuit is activated (ON), however, A/D conversion is not done. Therefore, the SA-ADC result register is not updated, A/D conversion termination interrupt does not occur, A/D conversion does not terminate automatically, and consequently, bit 0 (SARUN) of the SA-ADC control register (SADCON1) remains "1".

25.3 Description of Operation

25.3.1 Settings of A/D Conversion Channels

According to the setting of SA-ADC mode register 0 (SADMOD0), A/D conversion is performed as shown below and A/D conversion results are stored in the SA-ADC result register.

SA-ADC mode register 0		SA-ADC result register	Analog input
SACH0/1	0/1		
SACH0	0	SADR0	
SACH1	1	SADR1	AIN1 input
SACH0	1	SADR0	AIN0 input
SACH1	0	SADR1	
SACH0	1	SADR0	AIN0 input
SACH1	1	SADR1	AIN1 input

The values of the result register for the sections with a slash mark remain unchanged.
Do not start A/D conversion when bits 1 (SACH1) and 0 (SACH0) of SA-ADC mode register 0 (SADMOD0) are 0 and 0. If A/D conversion is started, the A/D conversion circuit is set to ON. However, as A/D conversion is not performed, the SA-ADC result register is not updated, an A/D conversion termination interrupt is not generated, A/D conversion does not terminate automatically, and bit 0 (SARUN) of the SA-ADC control register (SADCON1) remains "1".

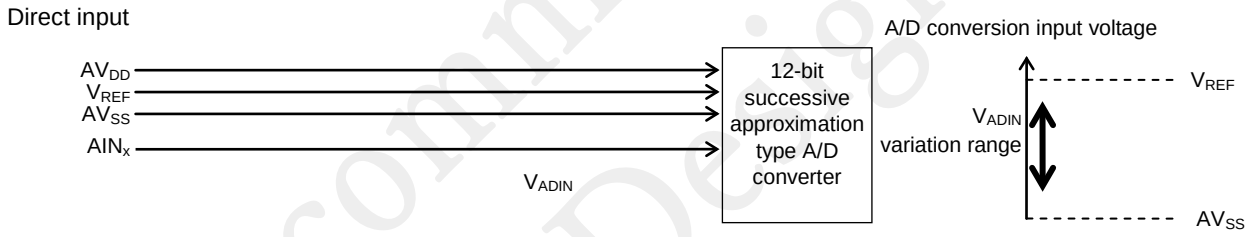

Figure 25-2 A/D conversion pins and conversion range

25.3.2 Operation of the Successive Approximation A/D Converter

1. Before starting SA-ADC, start oscillation of the high-speed clock (HSCLK) and wait until the oscillator settles.
2. Set the SA-ADC mode register 0 (SADMOD0).
3. When bit 0 (SARUN) of SA-ADC control register 1 (SADCON1) is set to "1", the SA-ADC circuit becomes active and performs A/D conversion from the lower channel number that is selected in the SA-ADC mode register (SADMOD0).
4. A/D conversion results are stored in the applicable SA-ADC result registers (SADRnL, SADRnH) and when A/D conversion of the largest channel number that is selected terminates, an SA-ADC conversion termination interrupt (ADSINT) is generated.
5. Finally, using bit 0 (SALP) of the SADCON0 register, it is possible to select whether A/D conversion is terminated (SARUN bit is "0") or A/D conversion is automatically restarted at termination of A/D conversion of the last channel.

Even if a channel is switched during A/D conversion, the channel that is selected at the start of A/D conversion is maintained until an A/D conversion termination interrupt occurs.
Figure 25-3 shows the SA-ADC operation timing when channel 0 and channel 1 are selected.

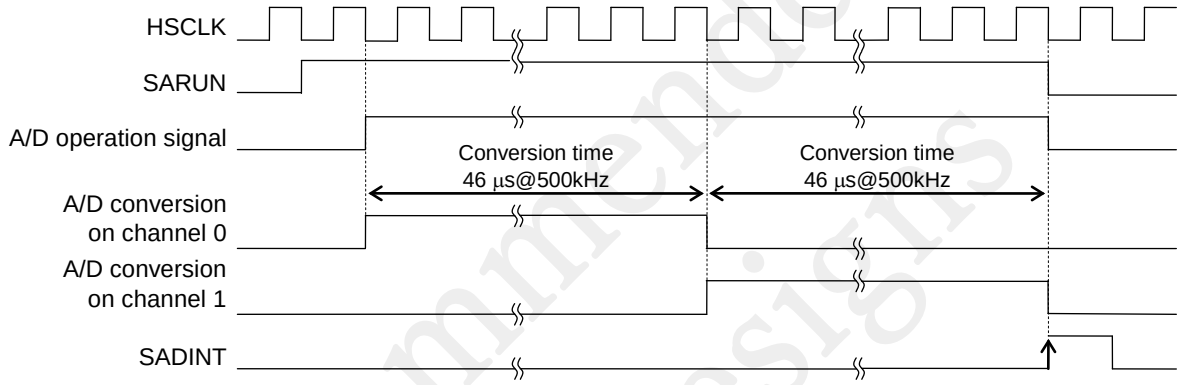

Figure 25-3 SA-ADC Operation Timing

Note:
A/D conversion time in 500kHzRC oscillation mode is 46 μs.

LCD Drivers

26. LCD Drivers

26.1 Overview

This LSI includes LCD drivers that display the contents that are set in the display register.
The LCD drivers handle the LCD display functions with three blocks.

1. Display registers
2. Display control
3. Drivers

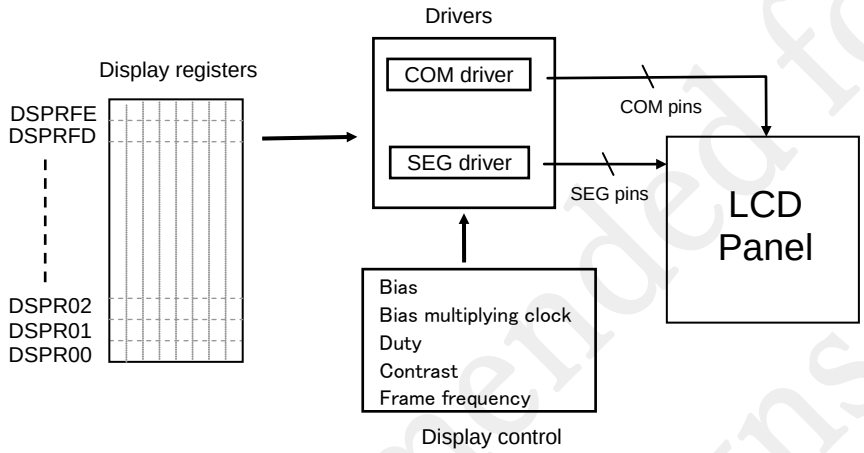

Figure 26-1 Configuration of LCD Display Function

The display registers are used to store the contents to be displayed as bit patterns.
The bit patterns depends on the specification of the LCD panel to be used (display pattern and assignment of the COM pin and SEG pin).

The display control circuit generates LCD drive waveforms according to the characteristics of the LCD.
A bias, a bias voltage multiplying clock, a duty, a frame frequency, and a contrast suitable for the LCD panel can be selected.

26.1.1 Features

The LCD drivers are applicable to various types of LCD panels. The features include:

26.1.3 Configuration of the Bias Generation Circuit

The bias generation circuit generates LCD drive voltages (V_{L1} to $V_{L3)}$ by multiplying the voltage (V_{L1}) generated by the voltage regulator with the capacitors (C_{12}).
When the BSON bit of the bias circuit control register (BIASCON) is set to "1", the bias generation circuit starts operation.
Display contrast adjustment is possible in 32 steps by using the display contrast register (DSPCNT).
Figure 26-3 shows the configurations of the bias generation circuit with 1/3 bias.

[Description of Bits]

- **ENBL** (bit 0)

The ENBL bit is used to control activation (ON) or deactivation (OFF) of the Battery Level Detector.
The Battery Level Detector is activated (ON) and deactivated (OFF) by setting the ENBL bit to "1" and "0", respectively.

ENBL	Description
0	Deactivates the Battery Level Detector (OFF) (initial value)
1	Activates the Battery Level Detector (ON).

- **BLDF** (bit 1)

The BLDF bit is the judgment result flag of the Battery Level Detector.
The BLDF bit is set to "1" or "0" when the power supply voltage (VDD) is lower than or higher than the threshold voltage selected by LD3 to LD0 bits of BLDCON0 register, respectively.

BLDF	Description
0	Higher than the threshold voltage (initial value)
1	Lower than the threshold voltage

27.3 Description of Operation

27.3.1 Threshold Voltage

The threshold voltage (VCMP) is selected by setting the bits of BLDCON0.
Table 27-1 shows the threshold voltages and the accuracy.

Table 27-1 Threshold Voltages and Accuracy

BLDCON0				Threshold voltage	Accuracy	Temperature
LD3	LD2	LD1	LD0	V_{CMP}	Ta = 25°C	deviation
0	0	0	0	1.35 V	±2.0%	±0.1%/°C
0	0	0	1	1.40 V		
0	0	1	0	1.45 V		
0	0	1	1	1.50 V

1	0	0	1	2.10 V		
1	0	1	0	2.20 V		
1	0	1	1	2.30 V		
1	1	0	0	2.40 V		
1	1	0	1	2.50 V		
1	1	1	0	2.70 V		
1	1	1	1	2.90 V		

27.3.2 Operation of Battery Level Detector

Activation (ON) and deactivation (OFF) of the Battery Level Detector are controlled by setting the ENBL bit of the Battery Level Detector control register (BLDCON1), and the result of the comparison of the power supply voltage (VDD) to the threshold voltage is output to the BLDF bit of BLDCON1.
When ENBL, the enable control bit of the Battery Level Detector, is set to "1", the detector is activated (ON). When ENBL is set to "0", the detector is deactivated (OFF) and has no supply current.
BLDF indicates the result of comparison. When BLDF bit is set to "1", it indicates the power supply voltage is lower than the threshold voltage. When BLDF bit is set to "0", it indicates the power supply voltage (VDD) is higher than the threshold voltage. The Battery Level Detector requires a settling time. Read BLDF bit 1ms or more after ENBL bit is set to "1".
Figure 27-2 shows an example of the operation timing diagram.

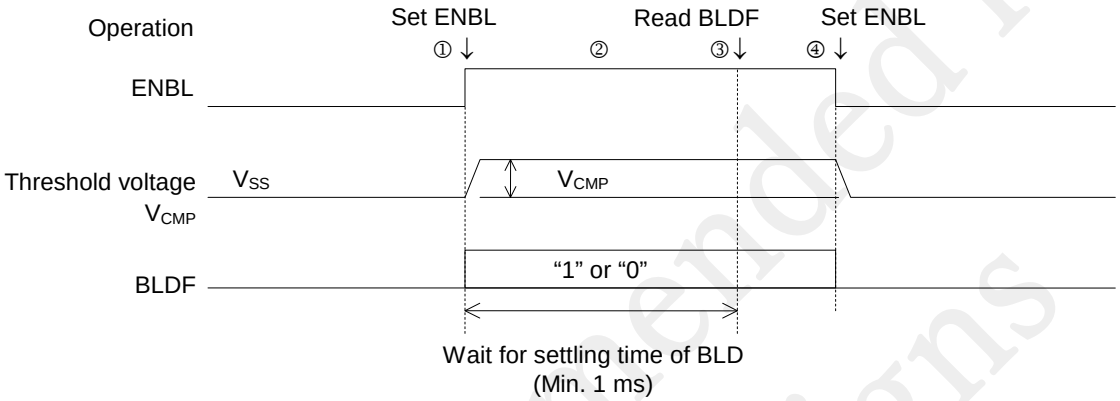

Figure 27-2 Example of Operation Timing Diagram

The operations in Figure 27-2 are described below.

① The Battery Level Detector is activated (ON) by setting the ENBL bit to "1".
② Wait the settling time (min. 1 ms) of the Battery Level Detector.
③ Read BLDF bit.
④ Set ENBL bit to "0".

Note:
Select the threshold voltage (VCMP) when the ENBL bit is "0".

Power Supply Circuit

28. Power Supply Circuit

28.1 Overview

This LSI includes a regulated power supply for the internal logic (VRL) and a regulated power supply for low-speed oscillation (VRX).
The VRL outputs the operating voltage, V_{DDL}, of the internal logic, program memory, RAM, etc.
The VRX outputs the operating voltage, V_{DDX}, for low-speed oscillation.
For the circuit configuration of the power supplies (AVDD, AVSS) for the analog circuits, see Chapter 25, "Successive Approximation Type A/D converter".
For the circuit configuration of the power supplies for LCD (VL1 to VL4), see Chapter 26, "LCD Driver".

28.1.1 Features

- VRL outputs the operating voltage, V_{DDL}, of the internal logic, program memory, RAM, etc.
- VRX outputs the operating voltage, V_{DDX}, for low-speed oscillation.

28.1.2 Configuration

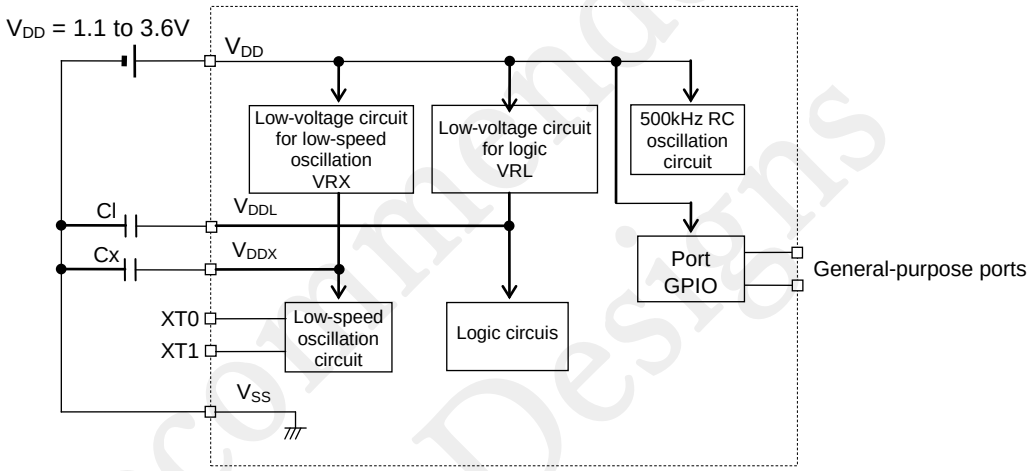

Figure 28-1 Configuration of Power Supply Circuit

28.1.3 List of Pins

Pin name	I/O	Description
V_{DDL}	—	Positive power supply pin for the internal logic circuits
V_{DDX}	—	Positive power supply pin for low-speed oscillation

28.2 Description of Operation

V_{DDL} and V_{DDX} become approx. 1.2 V at a system reset.
V_{DDX} becomes approx. 0.6 V (Typ.) after 4096 low-speed oscillation clock (XTCLK) pulses are counted after the system reset is released. As a result of release of STOP mode (generation of external interrupt), V_{DDX} becomes approx. 1.2 V(Typ.) and then approx. 0.6 V (Typ.) after 4096 low-speed oscillation clock (XTCLK) pulses are counted.

On-Chip Debug Function

29. On-Chip Debug Function

29.1 Overview

This LSI has an on-chip debug function allowing Flash memory rewriting.
The on-chip debug emulator (uEASE) is connected to this LSI to perform the on-chip debug function.

29.2 Method of Connecting to On-Chip Debug Emulator

Figure 29-1 shows connection to the on-chip debug emulator (uEASE).
For on-chip debug emulator, see "uEASE User's Manual".

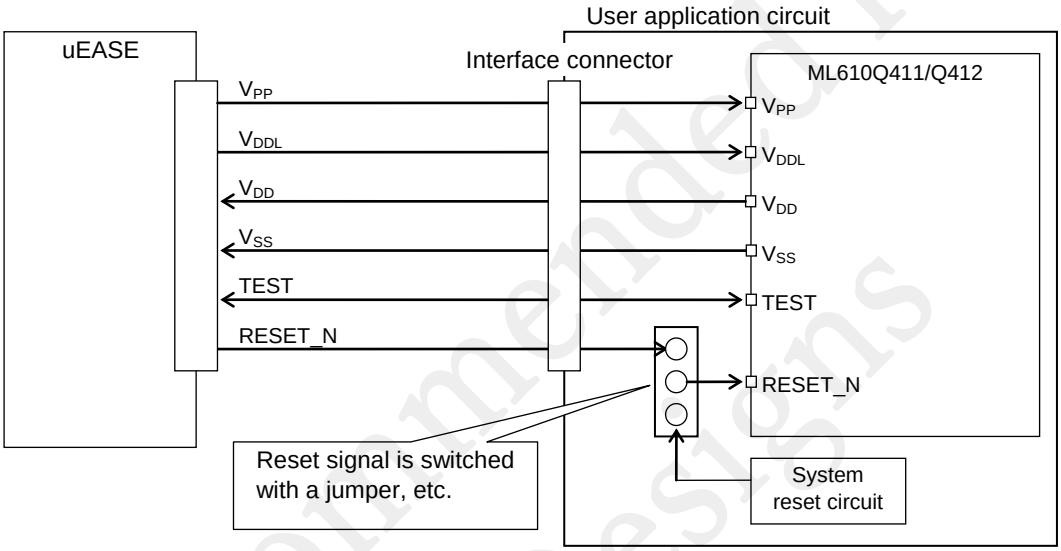

Figure 29-1 Connection to On-chip Debug Emulator (uEASE)

Note:
– Please do not apply LSIs used for debugging to mass production.
– When using the on-chip debug function or the flash rewrite function after mounting of the board, design the board so that the 5 pins (V_{PP}, V_{DD}, V_{SS}, RESET_N, and TEST_N) required for connection to the on-chip debug emulator can be connected.
– "3.0V to 3.6V" has to be supplied to VDD while debugging and writing flash.
– When the system reset circuit is included in the user application circuit, enable switching of the connection in the user application circuit, as shown above. When the system reset circuit is not included in the user application circuit, the RESET_N pin can be connected directy to the RESET_N pin of this LSI.

For details, see "uEASE User's Manual" and "uEASE Target Connection Manual".

29.3 Flash Memory Rewrite Function

Flash memory erase/write can be performed with the the memory mounted on board by using the commands from the on-chip debug emulator (uEASE). For more details on the on-chip debug emulator, see "uEASE User's Manual".
Table 29-2 shows the Flash memory rewrite functions.

Notes for Mounting the Surface Mount Type Package

The surface mount type packages are very susceptible to heat in reflow mounting and humidity absorbed in storage. Therefore, before you perform reflow mounting, contact a ROHM sales office for the product name, package name, pin number, package code and desired mounting conditions (reflow method, temperature and times).

Note:

- Please have the shortest layout for the common node (wiring patterns which are connected to the external capacitors, resistors and IN0/IN1 pin), including CVR0/CVR1. Especially, do not have long wire between IN0/IN1 and RS0/RS1. The

coupling capacitance on the wires may occur incorrect A/D conversion. Also, please do not have signals which may be a source of noise around the node.

- When RT0/RT1 (Thermistor and etc.) requires long wiring due to the restricted placement, please have VSS(GND) trace next to the signal.
- Please make wiring to components (capacitor, resisteor and etc.) necessory for objective measurement. Wiring to reserved components may affect to the A/D conversion operation by noise the components itself may have
