These considerations are important for assembly level programmers doing additional context save/restore (beyond what the ARP32 compiler does) and also to new custom instruction design for the ARP32 CPU if they depend on stack pointer relative operations.

8.2.7.4 General Restrictions

The ARP32 CPU has the following restrictions on the programming model:

- **Long Long (as 64 bit) is not supported natively in the architecture.** 'long long' is supported via emulation in the Run Time Support (RTS) library. Since this is non-standard and sub-optimal, use of long may severely degrade performance. Hence, it is highly recommended not to use the C 'long long' datatype.
- **64-bit arithmetic.** Add/sub of more than 32-bit values (operand or results) requires **ADDC/SUBC/BC** (addition with carry, subtraction with borrow, branch on carry) instructions that are not supported in the ARP32 CPU. Again, it is possible to emulate this in RTS but it is a sub-optimal implementation and it is not recommended.
- **Multi-threading via mutex is not supported in the architecture.** In the ARP32 CPU, it does not implement an "EXCLUSIVE access instruction" to implement a 'proper' mutex in RTS. A polling based multi-threading is still possible.

8.3 VCOP CPU and Instruction Set

NOTE: Throughout this section, various sample assembly code pieces are used to illustrate VCOP architecture and functionality. Programmers are expected to write code in VCOP Kernel-C, instead of in assembly.

8.3.1 Module Overview

The Embedded Vision Engine (EVE) module is a programmable imaging and vision processing engine, intended to be used in devices that serves consumer electronics imaging and vision applications. Its programmability allows late-in-development or post-silicon processing requirements to be met, and allows third party or customers to add differentiating features in imaging and vision products.

The EVE Module consists of an ARP32 scalar core, a VCOP vector core, and a DMA controller.

8.3.2 Features

- Interfaces
 - CLK/2 MHz custom interface with the scalar core
- Functionality
 - CLK MHz functional clock
 - Based on VICP coprocessor
 - Dual-issue, N-way SIMD per instruction
 - Scalable in N ways of SIMD, $N = \{2 | 4 | 8 | 16 | 32\}$
 - For the first version of VCOP $N = 8$
 - 16 entries x N ways x 40-bit register file
 - Binary morphology acceleration
 - N-way table lookup and histogram acceleration (capable of N lookups per cycle or N histograms per 4 cycle)
 - Up to 20-bit vector data memory address space
- Debug interface with visibility of loop variables and load/store pointers ([VCOP_LD_PTR_i](#)/[VCOP_ST_PTR_j](#)).

8.3.3 Block Diagram

The EVE subsystem contains an ARP32 scalar core, VCOP vector core, EDMA, memory blocks, memory switch, local interconnect, reset/clock, interrupt controller, SCTM and SMSET instrumentation blocks.

Figure 8-57 provides a block diagram.

Figure 8-57. EVE Block Diagram

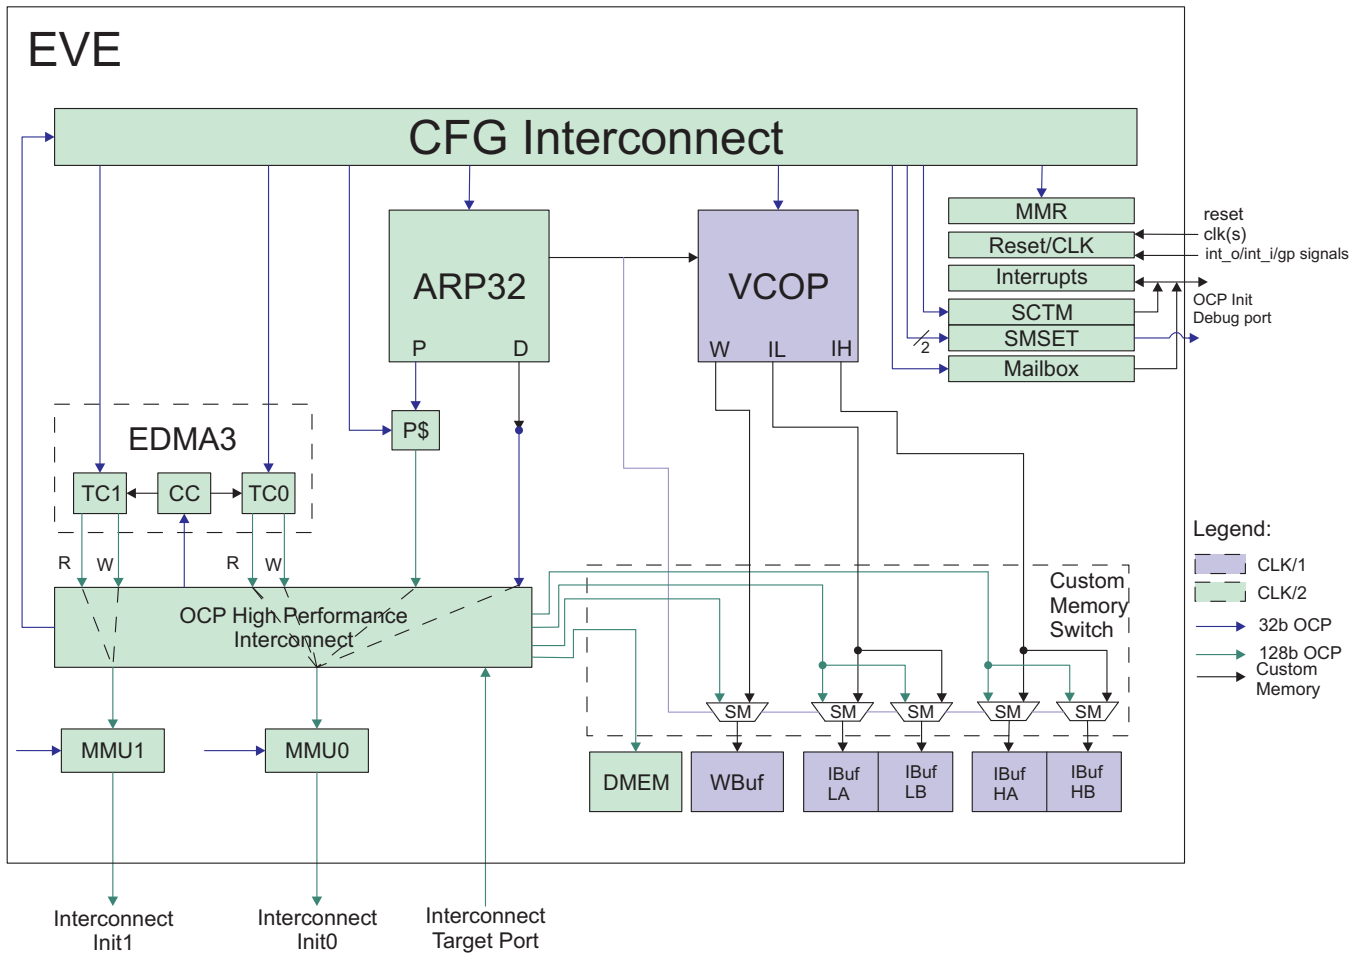

Figure 8-58 depicts the functional block diagram of EVE's Vector Coprocessor (VCOP).

Figure 8-58. VCOP Block Diagram

8.3.4 System Interfaces

8.3.4.1 Interrupts

The `vec_err_intn` interrupt is driven by the vector core and indicates that the vector core has encountered an error condition, see [Section 8.3.7.2.1 VCOP Register Manual](#) for details.

8.3.4.2 Configuration Bus Slave Port

VCOP has a configuration bus slave interface that follows the OCP 32-bit slave protocol. The interface enables module configuration, status, processor state readout during debug.

The interface operates in the same clock domain as `clk_eve_sca`, the scalar core and scalar/vector interface clock.

The memory map of the configuration bus is specified in [Section 8.3.7.2.1](#).

8.3.4.3 Performance Counter Interface

On the EVE level there is an SCTM module and an SMSET module to collect performance statistics.

SCTM is for counting signal active time and rise and fall transitions. SMSET is for conveying events to include into the system trace. [Table 8-352](#) lists the signals that are exported to SCTM or SMSET as indicated. All SCTM signals are level signals operating at full vector core speed (`clk_eve_vec`), and all SMSET signals are rising-edge triggered signals.

Table 8-352. Performance Counter Signal List

Signal	Destination	Description
vcop_busy	SCTM	Indicate VCOP busy, for measuring VCOP loading
vcop_idle_and_done	SCTM	Indicate VCOP idle and done, basically not(vcop_busy) and vec_done, for measuring slack in real-time schedule
vcop_wait_for_arp32	SCTM	Indicate VCOP idle and waiting for ARP32 to feed instruction, basically vec_rdy and not(vec_instr) and not(vcop_busy). This indicates VCOP under utilization that might be improved by reducing ARP32 interrupt services
vcop_arp32_awaits	SCTM	Indicate ARP32 has vector instruction ready and is waiting for VCOP to accept it, basically not(vec_rdy) and vec_valid. This indicates ARP32 idle time that might be utilized, however, not to the extent that vcop_wait_for_ARP32 time becomes significant.
vcop_overhead	SCTM	Indicate VCOP busy but not executing the loop, meaning exposed command decode (from decode-execute pipeline) and parameter access time. The former might be reduced by having more back-to-back loops, and the latter is unavoidable.
vcop_ld_stall_by_st	SCTM	Indicate LD stage is stalled by ST stage (forced write when write buffer is full). This means there is insufficient gaps in LD for ST to occur in the background, but this does not mean LD+ST is slowing down computation.
vcop_op_stall_by_ldst	SCTM	Indicate gaps in operation stage between iterations due to LD+ST, indicating extent of load/store bound (as opposed to compute-bound). This may be reduced by merging loops to reduce load/store.
vcop_op_stall_by_dependency	SCTM	Idle cycle inserted in operation stage due to dependency. This may be minimized by scheduling.
vcop_rd_ibufl	SCTM	Indicate VCOP reading from IBUFL
vcop_rd_ibufh	SCTM	Indicate VCOP reading from IBUFH
vcop_rd_wbuf	SCTM	Indicate VCOP reading from WBUF
vcop_wr_ibufl	SCTM	Indicate VCOP writing to IBUFL
vcop_wr_ibufh	SCTM	Indicate VCOP writing to IBUFH
vcop_wr_wbuf	SCTM	Indicate VCOP writing to WBUF
vcop_loop_start	SMSET	Indicate VCOP getting a VLOOP instruction
vcop_done	SMSET	Indicate VCOP executing a VWDONE instruction, copy of vec_done

8.3.4.4 Data Memory Map

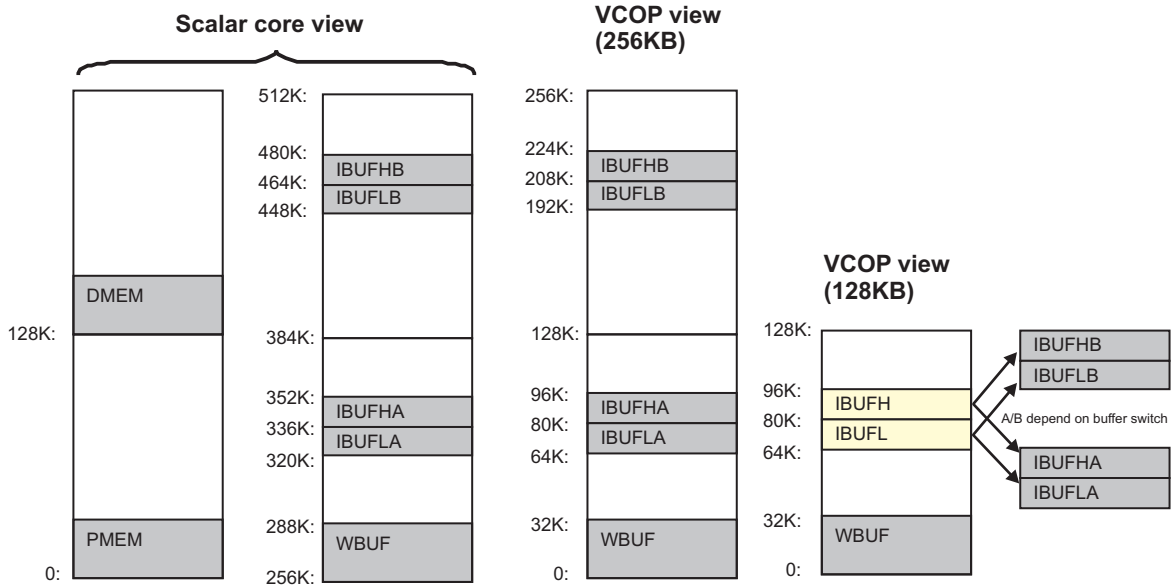

The first instance of EVE has a data memory configuration and a memory-map as listed in [Table 8-353](#).

Memory maps for scalar and vector core are shown in [Figure 8-59](#). An optional MMR field, VEC_MEM_128KB, wraps the VCOP memory map around 128KB, aliasing the A and B sets to the same address range.

Table 8-353. EVE Vector Data Memory Map

Byte Address	Name	Description
0x00000 ~ 0x07FFF	WBUF	Vector working buffer, 32Kbytes
0x08000 ~ 0x0FFFF	reserved	Reserved for future expansion
0x10000 ~ 0x13FFF	IBUFLA	Image buffer low copy A, 16 Kbytes
0x14000 ~ 0x17FFF	IBUFHA	Image buffer high copy A, 16 Kbytes
0x30000 ~ 0x33FFF	IBUFLB	Image buffer low copy B, 16 Kbytes
0x34000 ~ 0x37FFF	IBUFHB	Image buffer high copy B, 16 Kbytes

Figure 8-59. EVE Memory Map

8.3.5 Functional Description

8.3.5.1 Scalar-Vector Architecture

The EVE subsystem consists of a scalar core as the subsystem controller, a vector core as the high-throughput coprocessor, shared memories, DMA, clock/reset and interrupt controllers. See the *EVE Subsystem Reference Guide* for details.

8.3.5.1.1 Scalar Core

The scalar core executes conventional RISC instructions. The scalar core is based on the ARP32 processor.

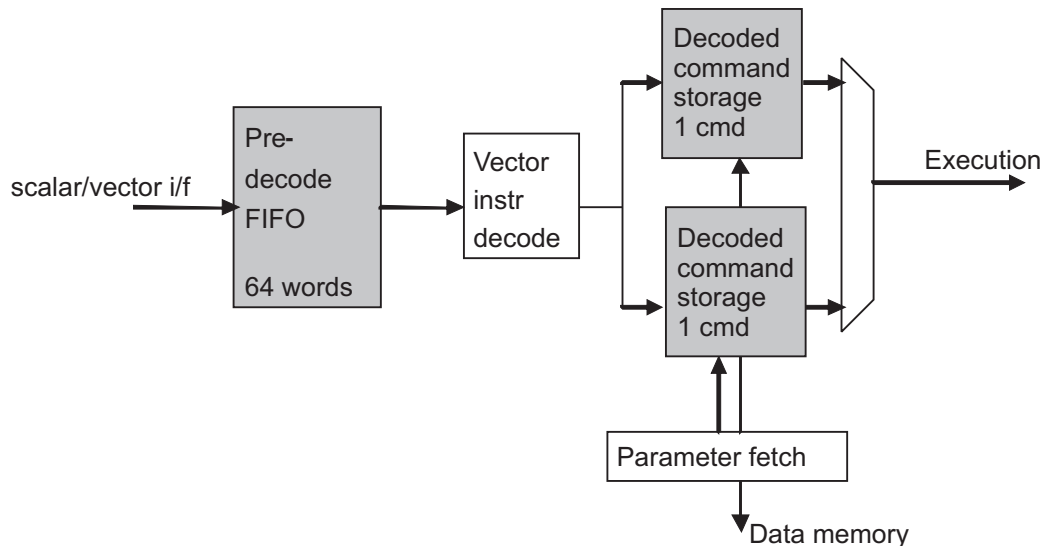

See the *ARP32 CPU and Instruction Set Reference Guide* for more details.

8.3.5.1.2 Scalar-Vector Interaction

The EVE scalar and vector cores share one program memory, but can execute in parallel on separate threads. The scalar core has sole control of the program memory, so all vector instructions are accessed by the scalar core, recognized being a vector instruction, and relayed via the scalar/vector interface to the vector core for execution. The vector core executes a sequence of instructions (called a vector command) repeatedly, so typically can be busy executing and does not need further vector instructions for thousands of clock cycles at a time.

The vector core has temporary instruction storage. There is a pre-decode buffer of 64 words, plus a decoded buffer for two maximal-sized commands (see [Figure 8-60](#)). The vector core attempts to decode and fill the two commands first, and if vector instructions keep coming, fill the pre-decode buffer. Together the buffering holds 4 or more typical vector commands, and keep the vector core busy for a while, allowing the scalar core to switch context to serve interrupts when interrupts occur.

Figure 8-60. VCOP Instruction Buffering

8.3.5.2 Vector Core Overview

The vector core is a SIMD machine with built-in loop control and address generation. It is programmed in array or 2D block processing level. The vector core has the following resources:

- 4 nested for loops, with loop variables i1, i2, i3, and i4, plus an optional outer loop i0
- 8 address generators, each capable of 4-dimensional addressing, that is, the address pattern is: $\text{base} + i1 \times \text{const1} + i2 \times \text{const2} + i3 \times \text{const3} + i4 \times \text{const4}$
- 16-entry vector register file, each entry is N-way SIMD \times 40-bit signed (sign-extended or zero-padded from 8/16/32-bit signed/unsigned memory data, or from operation upon register data)
- Two general-purpose functional units, each N-way SIMD. Functional spec supports $N = \{2 \mid 4 \mid 8 \mid 16 \mid 32\}$, first instance $N = 8$.
- Table lookup unit supporting up to N parallel lookups.
- Histogram unit supporting up to N parallel histogram operations.
- 8 load units
- 8 store units

The vector core supports the following functions:

- Generic compute
- Table lookup
- Histogram and weighted histogram

8.3.5.2.1 Nested for Loop Model

EVE vector operation is controlled by a four-level nested for loop. Inside the loop, the behavior can be represented in sequential stages: load, arithmetic operation, store, and pointer update.

In each stage, a number of load, operation, stores, or pointer updates are carried out, with respect to the $16 \times N \times 40$ -bit vector register file. There is no dependency among loads, stores, or pointer updates; multiple loads unto the same register file is not allowed. Dependency among operations assumes 2 operations are carried out in parallel, with no delay slot for most operations, and 1 cycle of delay slot for some specific operations.

The vector register file, loop variables, address generators are replicated as needed in the hardware to support pipelining among the various stages.

[Example 8-8](#) shows a skeleton of the nested loop model. There are four loop variables, i1, i2, i3, and i4. A snapshots of the loop variables are contained in the following registers:

- [VCOP_I0_I1\[15:0\]](#) I0 - I0 loop variable
- [VCOP_I0_I1\[31:16\]](#) I1 - I1 loop variable
- [VCOP_I2_I3\[15:0\]](#) I2 - I2 loop variable
- [VCOP_I2_I3\[31:16\]](#) I3 - I3 loop variable
- [VCOP_I4\[15:0\]](#)I4 - I4 loop variable

Example 8-8. Nested Loop Model Skeleton

```

EVE_compute(...)
{
    for (i1=0; i1<=lpend1; i1++) {
        for (i2=0; i2<=lpend2; i2++) {
            for (i3=0; i3<=lpend3; i3++) {
                for (i4=0; i4<=lpend4; i4++) {

                    for (k=0; k<num_inits; k++)
                        initialize_vreg_from_parameters(...);

                    for (k=0; k<num_loads; k++)
                        load_vreg_from_local_memory(...);

                    for (k=0; k<num_ops; k++)
                        op(...);          // 2 functional units, executing 2 ops per cycle

                    for (k=0; k<num_stores; k++)
                        store_vreg_to_local_memory(...);

                    for (k=0; k<num_agens; k++)
                        update_agen(...);
                }
            }
        }
    }
}
    
```

Each stage is described in more details in the following sections.

Note that loads and stores are predicated on the loop variables matching specific conditions and are thus not always carried out at every i4 iteration.

Each i4 iteration takes a number of cycles equal to the maximal number of cycles spent in loads, arithmetic operations, and stores. Cycle count in the arithmetic operations is constant for each loop, but cycle count in load and store can change depending on pointer update, loop level, and read/write memory contention.

For example, with $lpend1 = 3$, $lpend2 = 1$, $lpend3 = 2$, and $lpend4 = 4$, the nested for loop executes in exactly $4 \times 2 \times 3 \times 5 = 120$ i4 iterations. For the first few iterations the loop variables progress as:

i1	i2	i3	i4
0	0	0	0
0	0	0	1
0	0	0	2
0	0	0	3
0	0	0	4
0	0	1	0
0	0	1	1
0	0	1	2
...			

8.3.5.2.2 Instruction Organization

Vector instructions cannot appear in the program stream in arbitrary order. Instructions are classified as:

- Control
 - Repeat end count
 - Parameter pointer
 - Write buffer switch
- Synchronization
 - Wait for ready
 - Wait for done
- Computation
 - VLOOP
 - Register initialization
 - Address generator
 - Load
 - Operations
 - Store

The sequencing rule is that computation instructions that form a loop are in one contiguous block, starting with `VCOP_VLOOP_PTR[31:0]VLOOP_PTR`. This block of computation instructions is called a vector command. Control, synchronization, and scalar instructions can appear in any order, except that they cannot appear inside a vector command.

8.3.5.3 Vector Control

The VCTRL instruction is used to convey control information to the vector core. The instruction syntax is:

VCTRL <i>scalar_register, control_register</i>

The control registers so far defined are 0: RPT_END and 1: PARAM_PTR (VCOP_PARAM).

8.3.5.3.1 Repeat End Count

A VCTRL instruction variation programs the repeat end count. The syntax is:

VCTRL <i>scalar_register, RPT_END</i>
--

Subsequent VLOOP is executed RPT_END + 1 times. Reset default is 0, or repeating just once, and is the normal mode of operation. At end of loop execution, RPT_END is automatically reset to 0, so if the subsequent is non-repeating, which is most of the cases, there is no need to issue another VCTRL RPT_END to reset it.

RPT_END is a 12-bit value; the largest value supported is 0:4095, allowing for up to 4096 iterations of the repeat loop.

Note that the VLOOP instruction that follows can be of any type (computer, table lookup, histogram).

The repeat mechanism can be viewed as enclosing VLOOP by an outer loop, i0. The difference between this i0 loop and the i1, i2, i3, i4 loops inside VLOOP is that parameter pointer is advanced at the end of VLOOP. The repeat feature allows the same program code to be executed with a different set of parameters each time.

The repeat feature is useful for performing the same processing steps on a list of data regions that are not spaced regularly and/or not having the same dimension. Instead of having a scalar loop around the repeated VLOOP, using the repeat feature reduces scalar/vector interaction and resulting overhead.

Software must allocate memory appropriately to allow results of these data blocks to be stored (sequentially or otherwise is under programmer's control).

8.3.5.3.2 Parameter Pointer

In addition to the vector instructions in PMEM, the vector core must read a parameter file in WBUF or IBUFL/IBUFH (depending on the pointer value) before it begins intended computation. The parameters include loop counts, address pointers to arrays, constants used in the computation, round/truncate shift count, saturation bounds, etc. The parameter pointer is located in `VCOP_PARAM_PTR[31:0]` `PARAM_PTR`.

Separation of configuration coded in the program memory versus configuration conveyed in data memory is essential, as this allows library functions to be constructed with reasonable code size and can serve a variety of need in applications. Loop counts and address pointers being conveyed via parameters is needed, so that, for example, one filter function works for various data/coefficient/output arrays and block and coefficient kernel sizes. Round/truncation shifts being convey via parameters means that, for example, the same filtering kernel program can work for filters with different radix point bit positions for filter coefficients.

Parameter registers are 16-bit per entry in the parameter file, up to 64 entries. The first 2 entries of the parameter file, P0 and P1, are hard-coded to constant values 0 and 1 respectively, as these are commonly used and it reduces code size by referring to these constants without taking up data memory space.

Parameters are referred to in the vector instructions either as single register, 16-bit parameter, or as a register pair, together make up 32-bit. Where a pair is used, the first parameter must be an even index, and contains the lower 16-bit of the 32-bit.

From an application development point of view, algorithm kernels are sometimes coded in one vector command per kernel, sometimes in several commands. Thus it is beneficial for the vector core to advance the parameter pointer automatically to reduce overhead. This requires a mechanism to specify or modify the parameter pointer when needed. This is addressed by the parameter pointer update feature through `VCTRL`.

A `VCTRL` instruction variation updates the parameter pointer for the subsequent `VLOOP`. The syntax is:

VCTRL <i>scalar_register</i> , PARAM_PTR
--

Unless updated again by `VCTRL`, the parameter pointer is advanced automatically at the end of `VLOOP` execution by the `#PL` field of `VLOOP`. Thus, parameter blocks for multiple consecutive `VLOOPs` can be placed consecutively in data memory, and no `VCTRL` `VCOP_PARAM_PTR` is needed except for the first `VLOOP`.

For efficiency of parameter access by `VLOOP`, the pointer value conveyed via `VCTRL` must be 32-bit aligned. The parameter length specified in `VLOOP` is also 32-bit aligned. Thus, at the beginning of any `VLOOP`, the pointer is 32-bit aligned.

Note that inside a `VLOOP` while parameters are pulled off to configure the loop, the parameter pointer is only 16-bit aligned.

For example, if 11 parameter registers are used in a vector command, P0..10, the encoded parameter length is $\text{ceiling}((11 - 2)/2) = 5$. The subsequent next vector command accesses parameter registers 5 32-bit words from the current vector command, leaving one 16-bit halfword in memory unused.

8.3.5.3.3 Switch Buffers

To minimize task-switching overhead, an instruction is added to write to buffer switch MMR. The instruction syntax is:

VSWITCHBUF <i>ucst20</i>

Where `ucst20` is a 20-bit immediate value to be written to a dedicated MMR for buffer switches.

This instruction is carried out by the scalar core, and vector core just ignores it.

Change made to the buffer switch is visible in MMR as well, as both `VSWITCHBUF` and generic scalar core store to the buffer switch MMR are both valid ways to program the buffer switches, only that `VSWITCHBUF` achieves lower latency. Both mechanisms are kept consistent in the simulator/ debugger toolset.

8.3.5.4 Vector-Scalar Synchronization

8.3.5.4.1 Wait for Vector Core Done

The `VWDONE` instruction is used as a synchronization barrier between scalar and vector core, and affects the scalar/vector interface signal `vec_done`. Upon reset, `vec_done` is true. Upon execution of `VWDONE` in the scalar core, the scalar stalls and waits for `vec_done`. The vector core, upon executing this instruction, implying all previous submitted vector instructions are all done, asserts `vec_done`. Once asserted, `vec_done` stays true until receiving a subsequent `VLOOP` that turns the vector busy and `vec_done` false again.

The `VWDONE` instruction is typically used before the scalar core switches shared memory to itself or DMA. Before it changes the switch it makes sure that the vector core is idle and thus not accessing the memory.

`VWDONE` must appear between vector commands in the program, not inside a vector command.

8.3.5.4.2 Wait for Vector Core Ready

The `VWRDY` instruction is used to stall the scalar core until vector core is ready to accept additional vector instructions. Vector core ignores this instruction.

Normally the scalar core can simply issues vector instruction, and when the vector core is not ready, `VCOP_STATUS[2]VEC_RDY = 0` the scalar core is automatically stalled. Having `VWRDY` allows inserting timer read before and after `VWRDY` to measure the time duration of vector core not being ready, for performance tuning purposes.

8.3.5.5 Vector Computation

8.3.5.5.1 Vector Loop

The `VLOOP` instruction marks the beginning of a vector command specifying a loop. Assembly format:

<code>VLOOP</code> <i>cmd_type</i> , <i>CL#</i> : <i>cmd_len</i> , <i>PL#</i> : <i>param_len</i>
--

The `cmd_type` field specifies whether it is the main compute (COMP), table lookup (TLU), or histogram (HIST).

Command length (`cmd_len`) and parameter length (`param_len`) in 32-bit words are encoded to facilitate quick parsing of the vector commands. The ending loop counts, `lpend1/2/3/4`, are encoded at fixed entries in the parameter file, `P2 = lpend1`, `P3 = lpend2`, `P4 = lpend3`, `P5 = lpend4`. This allows easy adaptation of EVE function to different array dimensions.

The first two entries of the parameter file have implicit values and are thus not conveyed in the data memory. `P0 = 0` and `P1 = 1`. **The `param_len` does not include these two entries.**

The binary code of `VLOOP` includes a `version` field, which allows a compiler/assembler to indicate which version of EVE hardware the vector command is compiled for. The first version has `version = 0`, the next version, `version = 1`, and so on. This allows future version of EVE to offer backward compatibility; that is, execute previous-version binary as is. For example, if a future version of EVE has 16-way SIMD, it can execute 8-way SIMD binary by disabling half of the datapath.

Each vector command can have:

- Up to 8 address generators
- Up to 16 vector register initialization
- Up to 8 loads
- Up to 40 operations
- Up to 8 stores

Maximal command length is 81 instructions (VLOOP + 16 VINITs + 8 VAGENS + 8 VLDs + 40 operations + 8 VSTs).

8.3.5.5.1.1 Retention of State Between VLOOPS

From one VLOOP to the next VLOOP, the following state information is retained:

- Parameter pointer, advanced by parameter length in the first VLOOP
- Vector register contents, whatever left over from the last iteration of the first VLOOP

The following state information is not retained, thus must be configured within each VLOOP:

- Parameter register file (must be reloaded from data memory)
- Agen configuration, such as association of the four counts to parameter registers
- Agen address counter (reset at the beginning of each VLOOP execution)

8.3.5.5.2 Vector Register Initialization

It is useful to initialize vector register with constants provided in the parameter file. As parameter file is scalar (not NWAY SIMD), each value is broadcast to all NWAY of the destination vector register.

Assembly syntax:

VINIT *type_init_loop preg, vreg*

The data *type* can be signed/unsigned halfword or word. In case of word, two parameter register entries (16-bit each) are used, first one being copied to the lower halfword, and the second one to the upper halfword.

For the word type initialization, *preg* specified is the lower halfword and must be even. For example, *VINITWU_ONCE P10, V2* initializes V2 using $(P11 \ll 16) + P10$.

The *init_loop* field can be {ONCE, I234_ZERO, I34_ZERO, I4_ZERO, ALWS }.

The VINIT instruction is equivalent to initializing a specific vector register in the nested i1/i2/i3/i4 loop shown in [Section 8.3.5.3.2](#):

- ONCE is for initialization before the loop.
- I234_ZERO is for initialization inside the i1 loop, before entering the i2 loop.
- I34_ZERO is for initialization inside the i2 loop, before entering the i3 loop.
- I4_ZERO is for initialization inside the i3 loop, before entering the i4 loop.
- ALWS is for initialization inside the i4 loop, running every iteration.

The VINIT feature is used to initialize vector registers to certain initial values. For example, FIR filtering is implemented by iterating over filter taps with MADD instructions, and VINIT is used to initialize the accumulator to zero at the proper iteration, i4 for 1-D filter, and i3 for 2-D filter. Constants are brought into the computation loop with VINIT as well. For example, to scale an entire input array by a constant factor.

Note that VINIT broadcasts one value to all SIMD lanes. Initializing a vector register to multiple values is accomplished with a vector load (VLD) with zero address increment.

Sometimes it is useful to refer to loop variables in the computation. For example, to collect the maximal five values in an array and recording their indices, software can first do this in SIMD fashion to get to 5 sets of values and indices, then merge among SIMD lanes. Indices are readily copied from the loop variable i4, instead of spending cycles to compute with ALU operations.

VINIT provides this capability by extending the parameter count to cover loop variables:

- P64 = i0, the repeat outer loop enabled via VCTRL <scalar_reg>, RPT_END
- P65 = i1
- P66 = i2
- P67 = i3
- P68 = i4

When using these parameter counts, only the unsigned halfword type is supported.

8.3.5.5.3 Address Generator (agen)

In image, video, vision computation, there are often many operations performed on arrays of the same dimension; which can use the same addressing pattern (with different base addresses) in the memory read/write. The address generator resource is included to take advantage of this. One agen can be shared among multiple loads and/or multiple stores.

The VAGEN instruction has this assembly format:

```
VAGEN agen, [pinc4, pinc3, pinc2, pinc1]
```

Agen field is a label (A0..7) to identify one of 8 agen resources.

VAGEN is defined in strict linear order A0, A1, A2, till the last agen used in the command. The agens defined can be used (in loads and stores) in any order. It is allowed to share agen between load(s) and store(s).

The address increments represent:

- pinc4: inside the i4 loop, default
- pinc3: inside the i3 loop, when i4 matches the ending loop count
- pinc2: inside the i2 loop, when where i3 and i4 both match the ending loop counts
- pinc1: inside the i1 loop, when i2, i3, and i4 all match the ending loop counts

Figure 8-61 shows an example of 2 x 3 x 2 x 4 data object, addressed by the loop variables i1, i2, i3 and i4, with i1 being the outer-most loop. The address increments to access the object are shown in Figure 8-61.

Figure 8-61. Addressing a Four-Dimensional Data Object

In the VAGEN instruction, pointers to the parameter file are encoded, not the address increments themselves. Most data objects do not require 4-dimension addressing. For example, coefficient data for 2D FIR filter is normally stored consecutively, and advance by 1 data point most of the times, and wraps back at the end of i3 loop. Then $\text{pinc4} = \text{pinc3}$ is specified to one parameter register (initialized to 2 for 16-bit coefficients), and $\text{pinc2} = \text{pinc1}$ to another parameter register for the wrap-back. Thus, this scheme reduces command plus parameter data.

All address increments are in bytes. This allows misaligned halfword (16-bit) and word (32-bit) accesses that are some times needed in the processing.

Each address increment is encoded with one 16-bit parameter register, treated as signed value. The above example shows address increment moving forward, but in many cases, for example coefficients for filtering, negative increments are used.

Note that the address increments together specify addressing pattern of a single pointer, and the data distribution controls how consecutive memory data from that pointer, up to 32N-bit, are distributed among the SIMD dimension of the vector register entry.

In case multiple VAGEN instructions are issued for the same agen resource (for example, A0), the last one takes effect, and the preceding ones with the same agen resource is ignored.

8.3.5.5.4 Vector Load

The VLD instruction specifies the data distribution, data type, base address, agen, and the vector register to load the data to. Format of the VLD instruction in assembly is:

VLD *type_distribution base [agen], vreg*

The *base* field points to a pair of parameter registers (even/odd pair only), for example $\text{base} = \text{P8}$ to refer to the P8:P9 pair. The vector data memory space is 20-bit, with the lower 16-bit encoded in the even parameter register (P8 in this case), the upper 4-bit in the odd parameter register (P9 in this case).

The destination vector register specified in VLD must be an even register. VLD_DINTRLV loads into an even/odd pair of registers. VLD with any other distribution option loads into one register. There are up to eight VLD instructions in a loop to potentially load up all 16 registers. No register can be the destination of more than one VLD instruction in the same loop.

As EVE is an N-way SIMD machine, loading of N consecutive data points from local memory is supported, with each data point being a byte, short, or long (32-bit) word, either signed or unsigned.

In addition to loading N data points, EVE supports a few other distribution options. EVE supports the following:

- NPT: N data points, one to each way of SIMD
- 1PT: broadcasting one data point to all
- CIRC2: circuiting between two data points, useful for Bayer image processing
- DS2: downsample by 2; every other data point (**not available for word-size input**)
- US2: upsample by 2; repeat each input data point twice
- DINTRLV: deinterleave inputs; load 2N data points into two registers, deinterleave data items so that even items go to the first register, odd items go to the second register. Supported only for byte or halfword per data point, **not word data type**. Two registers must be an even/odd pair, but only the first register (even) is encoded in assembly and in instruction binary.
- CUST_P8: custom distribution as provided by {P8..} in the parameter file
- CUST_P16: custom distribution as provided by {P16..} in the parameter file
- CUST_P24: custom distribution as provided by {P24..} in the parameter file
- EXP: load with expansion using predicate register V0
- NBITS: N bits, one bit to each way of SIMD, regardless of the data type (for example, when $N = 16$, a halfword is read). Signed/unsigned data type affects how this bit is to be sign-extended. Unsigned means $0 \rightarrow 0$, $1 \rightarrow 1$, and signed means $0 \rightarrow 0$, $1 \rightarrow -1$. This is useful for expanding load and other cases where boolean arrays are packed.

For CUST_Pi options, number of bits required to specify the address offset for each way of SIMD depends on N, the number of ways of SIMD. Arbitrary distribution of N data items (each a byte, halfword, or word) is supported. For $N = \{2 \mid 4 \mid 8 \mid 16\}$, 4 bits is used to encode each destination. For $N = 32$, 5 bits is used; and each 16-bit parameter register supplies three fields (leaving 1 bit unused).

- $N = 2$, $2 \times 4 = 8$ bits, one parameter register required
- $N = 4$, $4 \times 4 = 16$ bits, one parameter register required
- $N = 8$, $8 \times 4 = 32$ bits, two parameter registers required
- $N = 16$, $16 \times 4 = 64$ bits, four parameter registers required
- $N = 32$, $\text{ceiling}(32/3) = 11$ parameter registers required

The DINTRLV option is supported so software can fully utilize the two function units for simple operation sequences, by processing 2N data points in parallel.

VLD instruction normally loads into one destination vector register. VLD_DINTRLV is the exception in that it loads into a pair of vector registers. Only even registers, V0, V2, ..., V14, can be referenced in the destination register field. In case of VLD_DINTRLV, the referenced register and the next register shall be the destination, for example V0 and V1.

The following data types are supported:

- B: signed byte
- BU: unsigned byte
- H: signed halfword (16-bit)
- HU: unsigned halfword
- W: signed word (32-bit)
- WU: unsigned word

Address offsets for each way of SIMD, as the function of distribution option and data type are shown in Table 8-354 and Figure 8-62, Figure 8-63, and Figure 8-64.

Table 8-354. VLD Data Distribution Options⁽¹⁾⁽²⁾

Distribution	vreg[r][0] gets	vreg[r][1] gets	vreg[r][2] gets	vreg[r][3] gets	vreg[r][4] gets	vreg[r][5] gets	vreg[r][6] gets	vreg[r][7] gets

DS2	data[0]	data[2]	data[4]	data[6]	data[8]	data[10]	data[12]	data[14]
US2	data[0]	data[0]	data[1]	data[1]	data[2]	data[2]	data[3]	data[3]
DINTRLV	vreg[r][0] = data[0], vreg[r+1][0] = data[1]	vreg[r][1] = data[2], vreg[r+1][1] = data[3]	vreg[r][2] = data[4], vreg[r+1][2] = data[5]	vreg[r][3] = data[6], vreg[r+1][3] = data[7]	vreg[r][4] = data[8], vreg[r+1][4] = data[9]	vreg[r][5] = data[10], vreg[r+1][5] = data[11]	vreg[r][6] = data[12], vreg[r+1][6] = data[13]	vreg[r][7] = data[14], vreg[r+1][7] = data[15]
CUST_Pi ⁽³⁾	data[pf[0]]	data[pf[1]]	data[pf[2]]	data[pf[3]]	data[pf[4]]	data[pf[5]]	data[pf[6]]	data[pf[7]]

⁽¹⁾ Table "data" is type-cast to the appropriate signed/unsigned byte/halfword/word so that correct offsets are applied.

⁽²⁾ This is a table of what data element gets loaded into each SIMD lane of a vector register, in the order lane 0 to lane 7. This does not reflect a debugger memory window hex display.

⁽³⁾ pf[0], pf[1], ... pf[7] refer to bit fields in the indicated parameter registers. For example, for the 8-way SIMD EVE, it takes two parameter registers for the distribution information, so for CUST_P8 use: $\text{distrib_info} = (\text{P9} \ll 16) \mid \text{P8}$, and assign $(\text{distrib_info} \gg (4 \times i)) \& 0xF$ to pf[i].

Loads are automatically predicated. Loads are always performed at the very first iteration, and then subsequently upon any change in the associated agen address pointer.

See [Section 8.3.5.5.10](#) for address alignment requirement for various data type and distribution options.

LD_EXP is load with expansion, and is for reading a compacted (collated) array and expanding the elements to the original locations. It is the opposite of ST_COLLAT (collating store). Per-item address increment is implied by the load data type (1/2/4 bytes depending on byte/halfword/word type). The agen field is don't care. Per iteration, load pointer ([VCOP_LD_PTR_i/VCOP_ST_PTR_j](#)) is increment by number of non-zeroes in predicate register V2 times the data size. Agen is not used, and so the agen field is not required in the assembly code:

VLD *type_EXP* *base*, *vreg*

For example with this instruction, where V2 = {0, 0, 1, 0, 1, 1, 0, 0}, load_ptr = 0x100:

```
LDBU_EXP Pbase[A0], V1
```

There shall be, after this instruction:

```
V1 = {0, 0, mem[0x100], 0, mem[0x101], mem[0x102], 0, 0}, and load_ptr = 0x103
```

Load with expansion is restricted to be used in table lookup VLOOP. This is because the dependency (where the expanding load depends on predicated register data from another load) is more similar to table lookup, and thus it's feasible to achieve N data points per clock cycle inside table lookup pipeline. As in normal table lookup, no operation instructions are allowed in table lookup VLOOP.

8.3.5.5.5 Vector Arithmetic/Logic Operations

Various arithmetic and logic operations are available in the compute command, which is indicated by starting the command with:

VLOOP COMP, *cmd_len*, *param_len*

Vector arithmetic/logic instructions have the following assembly formats, depending on whether it is 1-input-1-output, 2-input-1-output, 2-input-2-output, or 3-input-1-output, whether accumulator clearing is enabled, and whether rounding is enabled.

V<op_1i1o> src1, dst

V<op_2i1o> src1, src2, dst

V<op_2i1o> src1, src2, dst, RND: rnd_param

V<op_2i2o> src1/dst1, src2/dst2

V<op_2i2o> src1, src2/dst1, dst2

V<op_3i1o> src1, src2, src3, dst

V<op_3i1o> src1, src2, src3, dst, RND: rnd_param

All operations are 40-bit, except:

- Input to multiply (MPY, MADD, MSUB) is 17-bit data.
- BINLOG, BITC, BITDI, BITI, BITR are 32-bit instructions.
- BITPK, BITUNPK, SORT2, MIN, MAX are 33-bit instructions (to allow processing of up to 32-bit signed data)
- BITTR, bit transpose, bit width is limited to ways of SIMD, thus 8-bit data for 8-way SIMD.

The operations in [Table 8-355](#) are supported. See [Section 8.3.5.9](#) for details on each operation.

Table 8-355. VCOP Arithmetic/Logic Operations

Operation	#In- Out	#Bits	#Del	Syntax ⁽¹⁾	Note
VNOP		40		VNOP	
VADD	2-1	40		VADD src1, src2, dst	src1 + src2
VSUB	2-1	40		VSUB src1, src2, dst	src1 – src2
VABSDIF	2-1	40		VABSDIF src1, src2, dst	src1 – src2
VMPY	2-1	17/33	1	VMPY src1, src2, dst, RND:rnd_param	src1 * src2
VAND	2-1	40		VAND src1, src2, dst	src1 & src2
VOR	2-1	40		VOR src1, src2, dst	src1 src2
VXOR	2-1	40		VXOR src1, src2, dst	src2 ^ src2
VMIN	2-1	33		VMIN src1, src2, dst	min(src1, src2)
VMAX	2-1	33		VMAX src1, src2, dst	max(src1, src2)
VANDN	2-1	40		VANDN src1, src2, dst	src1 & (~src2)
VSHF	2-1	40/6		VSHF src1, src2, dst	src1 << src2, or src1 >> (-src2)
VRND	2-1	40/5	1	VRND src1, src2, dst	(src1 + (1 << (src2-1)) >> src2
VCMPSEQ	2-1	40		VCMPSEQ src1, src2, dst	(src1 == src2) ? 1 : 0
VCMPGT	2-1	40		VCMPGT src1, src2, dst	(src1 > src2) ? 1 : 0
VCMPGE	2-1	40		VCMPGE src1, src2, dst	(src1 >= src2) ? 1 : 0
VBINLOG	1-1	32	1	VBINLOG src1, dst	approximate binary log
VBITC	1-1	32	1	VBITC src1, dst	count one bits
VNOT	1-1	40		VNOT src1, dst	~src1

⁽¹⁾ The parameters src1, src2, src3, dst, dst2 refer to the vector register entry for source or destination.

Table 8-355. VCOP Arithmetic/Logic Operations (continued)

Operation	#In- Out	#Bits	#Del	Syntax ⁽¹⁾	Note
VMADD	3-1	17/40	1 / 2	VMADD src1, src2, src3, dst, RND: rnd_param	src3 + src1 * src2
VMSUB	3-1	17/40	1 / 2	VMSUB src1, src2, src3, dst, RND: rnd_param	src3 – src1 * src2
VADD3	3-1	40	1	VADD3 src1, src2, src3, dst	src1 + src2 + src3
VSAD	3-1	40	1	VSAD src1, src2, src3, dst	src3 + abs(src1 – src2)
VSEL	3-1	40		VSEL src1, src2, src3, dst	src1 ? src2 : src3
VAND3	3-1	40	1	VAND3 src1, src2, src3, dst	src1 & src2 & src3
VOR3	3-1	40	1	VOR3 src1, src2, src3, dst	src1 src2 src3
VSHFOR	3-1	40/6	1	VSHFOR src1, src2, src3, dst	src3 (src1 << src2) or src3 (src1 >> -src2)
VSORT2	2-2	33		VSORT2 src1/dst1, src2/dst2	dst1 = min(src1, src2) dst2 = max(src1, src2)
VBITPK	2-1	33	1	VBITPK src1, src2, dst	compare, bit-pack, broadcast
VBITUNPK	2-1	40	1	VBITUNPK src1, src2, dst	bit unpack
VEXITNZ		40		VEXITNZ level, src1	exit loop at end of iteration when (src1 != 0)
VCMOV		40		VCMOV cond, src1, dst	conditional move
VBITR	1-1	32	1	VBITR src1, dst	bit reverse
VBITI	2-1	32	1	VBITI src1, src2, dst	bit interleave
VBITDI	1-2	32		VBITDI src1, dst1, dst2	bit deinterleave
VABS	1-1	40		VABS src1, dst	abs(src1)
VADDH	2-1	40		VADDH src1, src2, dst	src1+ signext(src2[39:32])
VLMBD	3-1	40	1	VLMBD src1, src2, dst	left-most-bit-detect
VBITTR	1-1	NSIMD	1	VBITTR src1, dst	bit transpose
VSIGN	2-1	40		VSIGN src1, src2, dst	apply sign of src1 on src2
VADDSUB	2-2	40		VADDSUB src1/dst1, src2/dst2	dst1 = src1 + src2 dst2 = src1 – src2
VINTRLV	2-2	40		VINTRLV src1/dst1, src2/dst2	interleave
VDINTRLV	2-2	40		VDINTRLV src1/dst1, src2/dst2	deinterleave
VMINSETF	2-2	33		VMINSETF src1, src2/dst1, dst2	minimum and set flag
VMAXSETF	2-2	33		VMAXSETFsrc1, src2/dst1, dst2	maximum and set flag
VINTRLV2	2-2	40		VINTRLV2 src1/dst1, src2/dst2	interleave with 2-element frequency
VDINTRLV2	2-2	40		VDINTRLV2 src1/dst1, src2/dst2	deinterleave with 2-element frequency
VINTRLV4	2-2	40		VINTRLV2 src1/dst1, src2/dst2	interleave with 4-element frequency
VSHF16	1-2	33		VSHF16 src1, dst1, dst2	shift up 16 bits into 2 registers
VADIF3	3-1	40	1	VADIF3 src1, src2, src3, dst	add difference, dst = src1 – src2 + src3
VSWAP	3-2	40		VSWAP cond, src1/dst1, src2/dst2	conditional swap

Operations with two destinations must use two different destination registers, otherwise the outcome is undefined.

The accumulating register (being a source as well as the destination of an operation) must be src1 for 2-input-1-output operations, and must be src3 for 3-input-1-output operations.

The rounding parameter is needed for VMPY, VMADD and VMSUB instructions, and specifies an index to the parameter file, see [Section 8.3.5.9](#).

EVE hardware executes up to 2 operations in parallel per clock cycle. Assembly program (by programmer or by compiler) contains the parallel bar notation to indicate if an instruction is to be executed by itself, or is to be executed in parallel with another instruction.

VMADD, VMSUB instruction have two delay slots for the multiplication input, and one delay slot for the addition/subtraction input.

VMPY, VRND, VBINLOG, VBITC, VADD3, VSAD, VAND3, VOR3, VSHFOR, VBITPK, VBITUNPK, VBTR, VBITI, VLMBD, VBITTR, VADIF3 instructions have one delay slot.

All other operations do not have delay slots.

The hardware detects and treats write/read dependency between any two sequential instructions, but not inside parallel executed instruction pairs. When necessary for correctness, hardware inserts idle cycles automatically. Still to achieve good performance, software must try to schedule the operations to avoid automatic idle cycles.

There is a forwarding path *within each* functional unit and *between* the two functional units to forward from destination to source 3 (accumulator input) of 3-input-1-output operations.

Register forwarding, dependency checking and automatic idle cycle insertion work across iterations as well, from end of one iteration to the beginning of the next iteration. For example, the FIR filtering kernel executes in one cycle per iteration with the destination-to-source3 dependency across iterations.

[Table 8-356](#) shows delay slots and automatically inserted idle cycles.

Table 8-356. Example of Operation Delay Slots

Time	VMPY	VMADD	VSUB	VMSUB	VAND	VOR	VADD
0	V0*V1						
1	V0*V1 => V7	V2*V3	V2-V6 => V6				
2		V2*V3 => p		V4*V5	V3 & V6 => V6		
3		V7 + p => V7		V4*V5 => p		wait for V7	
4				V7 - p => V7		wait for V7	
5						V1 V8 => V9	V6 + V7 => V6

Zero-delay slot operation executes in one cycle. VMPY, an one-delay slot operation takes two cycles to execute. VMADD and VMSUB, two-delay slot operations take 3 cycles for execution, but need its additional input only on the third cycle. The dependency between the two instructions (VMADD-VMSUB) on the additional operand does not introduce idle cycles, but VMSUB-VADD dependency adds 2 idle cycles to execution per iteration.

8.3.5.5.6 Vector Store

The VST instruction specifies the data distribution, data type, base address (index to parameter file), *agen*, the vector register to get the store from, loop level when stores are to occur, and rounding/saturation configuration. Format of VST is:

```
[pred] VSTtype_ distribution_wr_loop vreg, base[agen], RND_SAT: rnd_sat_param
```

Storing of up to N data points from vector register to local memory is supported, with each data point being a byte, short, or long (32-bit) word, either signed or unsigned. Signed/unsigned information is used in performing saturation.

There are up to eight VST instructions in one loop, and each VST can be from the full vector register file, V0..V15. It is allowed to overlap the source registers, i.e., having more than one VST instructions storing out the same vector register. Also, in the extreme case of having all eight VST being interleaving stores, all 16 vector registers can be written out.

There is a further constraint on source registers for vector store. Only V0, V1, V2, and V3 can be stored without being the destination of any operation.

VCOP supports the following store patterns:

- NPT: For 8-way SIMD, 8 data points
- 1PT: write only the first SIMD unit
- DS2: downsample by 2; every-other SIMD units are written
- INTRLV: interleave outputs; store 2N data points from two registers interleaved. Two registers must be an {i, i+1} pair (i = 0..14), but only the first register (i) is encoded in assembly and in instruction binary. Byte and halfword types are supported, but not word type. It is NOT allowed to predicate interleaving stores. (If one must predicate interleaving store, use VINTRLV operation to interleave two sets of N data points, then use two predicated VST<type>_NPT.)
- OFFST_NP1: write out all N data points, in (N + 1) words = (4N + 4) bytes address increments (for transposition). Note that although address offset is word-aligned, storing to partial word, in case of byte and halfword types, are supported. In case of byte or halfword type, the 2 LSBs of address determines the byte or halfword within each word that VCOP writes data into.
- COLLAT: collating store, use predicate register to indicate store/not-store, up to N data items stored per cycle, *agen* is don't care, and hardware increments store address by the size implied by the data type. The *agen* field is not required in the assembly code:

```
[pred] VSTtype_ COLLAT_wr_loop vreg, base, RND_SAT: rnd_sat_param
```

- SDDA: sequential data-driven addressing, taking M cycles to store M data points (predication can lead to less than N stores), store Vreg[i] to address base + *agen* + V0[i] Note that *agen* can be used to vary the pointer, in addition to V0. Only unsigned address offset in V0 is supported.
- PDDA: parallel data-driven addressing. Use this mode when address offsets in V0 is such that all lanes enabled for store go to separate memory banks. Hardware executes the store of up to N data points in one cycle. In case there is bank conflict, outcome is indefinite, and an error interrupt is generated.
- SKIP: store N data points into every other elements in memory. Allowed for byte and halfword types, not for word type.

The following data types are supported:

- B: signed byte
- BU: unsigned byte
- H: signed halfword (16-bit)
- HU: unsigned halfword
- W: signed word (32-bit)
- WU: unsigned word

Table 8-357. EVE ST Data Distribution Options for NWAY = 8⁽¹⁾⁽²⁾

Distribution	vreg[r][0] goes to	vreg[r][1] goes to	vreg[r][2] goes to	vreg[r][3] goes to	vreg[r][4] goes to	vreg[r][5] goes to	vreg[r][6] goes to	vreg[r][7] goes to
NPT	dptr[0]	dptr[1]	dptr[2]	dptr[3]	dptr[4]	dptr[5]	dptr[6]	dptr[7]
1PT	dptr[0]	n/a	n/a	n/a	n/a	n/a	n/a	n/a
DS2	dptr[0]	n/a	dptr[1]	n/a	dptr[2]	n/a	dptr[3]	n/a
INTRLV	dptr[0] = vreg[r][0], dptr[1] = vreg[r+1][0]	dptr[2] = vreg[r][1], dptr[3] = vreg[r+1][1]	dptr[4] = vreg[r][2], dptr[5] = vreg[r+1][2]	dptr[6] = vreg[r][3], dptr[7] = vreg[r+1][3]	dptr[8] = vreg[r][4], dptr[9] = vreg[r+1][4]	dptr[10] = vreg[r][5], dptr[11] = vreg[r+1][5]	dptr[12] = vreg[r][6], dptr[13] = vreg[r+1][6]	dptr[14] = vreg[r][7], dptr[15] = vreg[r+1][7]
OFFST_NP1	dptr[0]	dptr[9]	dptr[18]	dptr[27]	dptr[36]	dptr[45]	dptr[54]	dptr[63]
COLLAT	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++
SDDA/PDDA	dptr[V0[0]]	dptr[V0[1]]	dptr[V0[2]]	dptr[V0[3]]	dptr[V0[4]]	dptr[V0[5]]	dptr[V0[6]]	dptr[V0[7]]
SKIP	dptr[0]	dptr[2]	dptr[4]	dptr[6]	dptr[8]	dptr[10]	dptr[12]	dptr[14]

(1) Table “dptr” is type-cast to the appropriate signed/unsigned byte/halfword/word so that correct offsets are applied. dptr = base + agen.
 (2) Custom distribution is not supported for stores.

Stores are predicated to perform at the indicated loop level, with wr_loop selectable from:

- ALWS: write out on every i4 iteration
- LAST_I4: write out on the last i4 iteration, when i4 = lpend4
- LAST_I34: write out on the last i3 iteration, when i3 = lpend3 and i4 = lpend4
- LAST_I234: write out on the last i2 iteration, when i2 = lpend2, i3 = lpend3, and i4 = lpend4

Rounding and saturation arithmetic is available in the store pipeline to provide rounding and saturation without taking additional cycles.

Rounding and saturation parameters are provided in the parameter file to allow easy adaptation of EVE functions to different rounding and saturation configurations. The rnd_sat_param field in the instruction points to a parameter (instruction encoding limits this field to 5 bits, thus restricting it to P0..P31) that contains the following fields shown in [Figure 8-65](#).

Figure 8-65. VST Rounding and Saturation Parameters

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sat_mode: 0 = NO_SAT 1 = SYMM 2 = ASYMM 3 = 4PARAM 4 = SYMM32 5 = ASYMM32			sat_bound_param: index to param that specifies saturation bound						rnd_mode: 0 = no rounding 1 = round 2 = truncate			rnd_shift: number of bits to round/shift down			

The following saturation modes are supported:

- NO_SAT: no saturation performed
- SYMM: signed symmetrical saturation [-bound, bound] (for unsigned store, [0, bound])
- ASYMM: signed asymmetrical saturation [-bound-1, bound] (for unsigned store, [0, bound]), useful for fixed bit width. For example, when bound = 1023, saturate to [-1024, 1023]
- 4PARAM: use 4 parameter registers to specify sat_high_cmp, sat_high_set, sat_low_cmp, sat_low_set.
- SYMM32: same as SYMM, except using a pair of parameters to specify a 32-bit bound
- ASYMM32: same as ASYMM, except using a pair of parameters to specify a 32-bit bound

Signed/unsigned designation is on the VST type, and signed/unsigned designation affects whether the bound parameter(s) are interpreted as signed or unsigned. The comparison is carried out between signed 40-bit register and such interpreted bounds.

When no rounding and saturation feature is needed, specifying RND_SAT: P0 is working, since constant 0 in these fields represents doing nothing.

Conditional store is specified by the pred field. Omission means no predication. Pred = V1, V2, V3 indicates that register V1, V2, V3 is used to predicate the store of each way of SIMD; store is executed when the register is not zero.

With the COLLAT distribution option, all SIMD ways are examined for conditional store. Truth in the predication register leads to the data item being stored and incrementing of the data pointer by size of the store type (1/2/4 bytes). False in the predication register leads to doing nothing. Thus, stored data items are compacted without leaving any gaps for the blocked data items.

With other distribution options, conditional store behaves differently. Agen is incremented as in unconditional stores. Truth in the predication register leads to the data item being stored, and false in the predication register leads to the data item being skipped. Thus, it is possible for the stored data items to contain gaps among them from the blocked data items.

The store stage hardware has separate resource for each VCOP data memory region (IBUFL, IBUFH, WBUF). Sequential data-driven store is executed in X cycles, X being the number of data items enabled in predication (or when predication is not used, N). The other store modes are executed in a single cycle per store (note that collating store executes in one cycle as well). All memory regions are carried out in parallel, but there is also potential memory contention with the load stage. There is write buffering in the store stage to reduce load/store contention to some degree. See [Section 8.3.5.6](#) for load/store buffering details.

8.3.5.5.7 Table Lookup Operation

Table lookup operation is indicated by starting the vector command with

VLOOP TLU, *CL#:cmd_len, PL#: param_len*

The table lookup operation uses a subset of the available resources and instructions:

- VAGEN (address generator): fixed A0 for data, A1 for table pointer, A2 for output.
- VLD (load): one for loading data into V2.
- VTLD (table load): for performing the lookup, using V2 as indices to load table entry into V0.
- VST (store): for storing outcome in V0.
- Full set of 4 levels for looping.

The table pointer is allowed to move via agen, to allow loop-variable-dependent manipulation of table base. For example, software might process three color components (RGB or YUV), each having a different table, in the same command, and use the outer loop variables to index among the color components and the corresponding tables.

Data is loaded with normal load into V2, for example:

```
VLDBU_1PT      data_base[A0], V2
```

The data load using VLD has access to a subset of load distribution options: {NPT, 1PT, DS2, US2}.

- 1PT works for single table configuration
- NPT works for all other cases of normal table lookup
- DS2 and US2 provides additional flexibility to downsample/upsample data

A special table load, VTLD, is used for the lookup:

VTLD*type_m TBL_nPT tbl_base[tbl_agen][V2], V0, RND_SAT:rnd_sat*

Normally lookups only fetch one item per lookup. Multiple items are useful for bilinear and bicubic interpolations. The `_mTBL` field in VTLD specifies the number of parallel tables and the `_nPT` field in VTLD specifies the number of data items per lookup table.

There are constraints on `num_par_tbl`, `num_data_per_lu`, and the table data size:

- $\text{num_par_tbl} \times \text{num_data_per_lu} \leq N$ (ways of SIMD)
- $\text{num_data_per_lu} = \{1 \mid 2 \mid 4\}$ regardless of N (ways of SIMD)

Constraints for 8-way SIMD architecture are shown in [Table 8-358](#).

Table 8-358. Lookup Constraints for 8-Way SIMD

Table type	Num items per lookup, num_data_per_lu	Number of parallel tables, num_par_tbl			
		1	2	4	8
Byte	1	√	√	√	√
	2	√	√	√	
	4	√	√		
	8	√			
Half word	1	√	√	√	√
	2	√	√	√	
	4	√	√		
	8	√			
Word	1	√	√	√	√
	2	√	√	√	
	4	√	√		
	8	√			

Results are stored back to memory with a normal data store as in compute loop with simplification:

`VSTtype_distribution_ALWS V0, base[agen], RND_SAT: rnd_sat_param`

This VST has access to a subset of store distribution options: {NPT | SKIP}.

Number of data points that are stored per i4 iteration is $\text{num_data_per_lu} \times \text{num_par_tbl}$ from the table load, and this is an implicit predication.

For example, when there is table load `VTLDHU_1TBL_2PT`, the store `VSTHU_NPT` is not storing N points, but just 2 point.

In forming the indices for lookup, data are read in, rounded and saturated. Rounding and saturation parameters are specified in VTLD's `RND_SAT: rnd_sat` field. This field is 5-bit (like VST), so only P0..P31 is allowed. The same set of round/saturate parameters as the normal store, VST, are used. VTLD's `RND_SAT` is for round/saturate the data to form table lookup index. VST also contains a `RND_SAT` field, which is used to round/saturate looked up table entries before storing back to data memory.

Various other table lookup parameters are extracted from the instructions:

- Input data type is from `VLDtype`, and is limited to unsigned types.
- Table entry type is from `VTLDtype`, and can be signed or unsigned although the signed/ unsigned information is not used.
- Output type is from `VSTtype`, can be signed or unsigned, and can be different from the table entry type. Signed versus unsigned information is used for saturation.
- Input data distribution is from `VLD V2`, with SIMD units $0..\text{num_par_tbl}-1$ used for the lookup.
- Output distribution option is either NPT, storing consecutively (which may not be N points), or SKIP, storing to every other memory location.

- Table entries are read into the vector register SIMD lanes by iterating on `num_par_tbl` in the outer loop, and `num_data_per_lu` in the inner loop. For example, with `num_par_tbl = 2` and `num_data_per_lu = 4`, with `VSTBU_NPT` we have:

```
V0[0] = tbl_base[data0],      V0[1] = tbl_base[data0 + 1],
V0[2] = tbl_base[data0+2],    V0[3] = tbl_base[data0 + 3],
V0[4] = tbl_base[data1],      V0[5] = tbl_base[data1 + 1],
V0[6] = tbl_base[data1+2],    V0[7] = tbl_base[data1 + 3]
```

Table organization in memory depends on table type and `num_par_tbl`. The `N` physical banks of 32-bit memory is partitioned into `num_par_tbl` logical banks, and each parallel table is organized inside its own bank.

For example, when `NWAY = 8`, you can have 1, 2, 4, or 8 parallel tables. Data organization for these and byte, halfword, and word type entries is shown in [Figure 8-66](#).

A few examples of the table lookup operation follow. The `NPT` distribution for load and store works for normal lookup scenarios.

; single table, byte data, short table/output

```
VLOOP          TLU, #cmd_len, #param_len
VAGEN          A0, ...
VAGEN          A1, ...
VAGEN          A2, ...
VLDBU_1PT     data_base[A0], V2                ; load data to V0
VTLDHU_1TBL_1PT table_base[A1][V2], V0, RND_SAT: rnd_sat ; look up
VSTH_NPT_ALWS V0, outp_base[A2], RND_SAT: rnd_sat_st ; store outcome
```

; 4 parallel tables, 2 items per table, short data, byte table/output

```
VLOOP          TLU, #cmd_len, #param_len
VAGEN          A0, ...
VAGEN          A1, ...
VAGEN          A2, ...
VLDHU_NPT     data_base[A0], V2                ; load data to V0
VTLDHU_4TBL_2PT table_base[A1][V2], V0, RND_SAT: rnd_sat ; look up
VSTB_NPT_ALWS V0, outp_base[A2], RND_SAT: rnd_sat_st ; store outcome
```

Load with expansion can only be used in a table lookup loop. An example follows.

; load with expansion, short input data, unsigned byte flags, short expanded output

```
VLOOP          TLU, #cmd_len, #param_len
VAGEN          A0, ...
VAGEN          A2, ...
VLDBU_NPT     flag_base[A0], V2                ; load flags to V2
VLDH_EXP      input_base, V0                    ; load with expansion
VSTH_NPT_ALWS V0, outp_base[A2], RND_SAT: rnd_sat_st ; store outcome
```

For example, in a particular iteration, suppose there are flags `V2 = {0, 0, 1, 0, 1, 1, 0, 0}`, and the expanding load pointer = `0x100` before the expanding load. After the expanding load:

```
V0 = {0, 0, mem[0x100], 0, mem[0x102], mem[0x104], 0, 0}
```

The pointer is advanced to `0x106`, incremented by 3 (number of nonzero flags) times the size of data type (2 bytes for halfword).

Optionally, predicated store can be used while writing the expanded outcome array, leaving `flag==0` data points unaltered.

```
VLOOP          TLU, #cmd_len, #param_len
VAGEN          A0, ...
VAGEN          A2, ...
VLDBU_NPT     flag_base[A0], V2                ; load flags to V2
VLDH_EXP      input_base, V0                    ; load with expansion
[V2] VSTH_NPT_ALWS V0, outp_base[A2], RND_SAT: rnd_sat_st ; store where V2 != 0
```

Performance of load with expansion is `NWAY` expanded data points per cycle when there is no memory contention, by pipelining the flag load, data load, and output store.

8.3.5.5.8 Histogram Operation

Histogram functionality includes normal histogram, in which the addressed bin entry is incremented by 1, and weighted histogram, in which the addressed bin entry is incremented by an element in the weight array input.

Histogram operation is indicated by starting the vector command with:

VLOOP HIST, *CL#*: *cmd_len* , *PL#*: *param_len*

The histogram operation uses a subset of the available resources and instructions:

- VAGEN (address generator): fixed A0 for data, optional A1 for histogram input/output pointer, A2 for weights
- VINIT (register initialization) for normal histogram, providing a fixed increment value (normally 1)
- VLD (load): one load for data, and in the case of weighted histogram, one additional load for weights
- VHLD (histogram load): load histogram bins
- VADD (add) to increment histogram bins
- VHST (histogram store): store histogram bins back to memory
- Full set of 4 levels for looping

For normal histogram, the increment value is initialized via a VINIT instruction on V4:

```
VINITHU_ONCE P1, V4
```

Data is loaded with normal load into V2, for example,

```
VLDBU_NPT data_base[A0], V2
```

Distribution options of VLD are {1PT, NPT, DS2, US2}. 1PT works for single histogram configuration, NPT works for 2, 4, or 8 parallel histograms.

Optional weights (for weighted histogram) are loaded with another normal load into V4, for example,

```
VLDBU_NPT weight_base[A1], V4
```

A special histogram load, VHLD, is used to read in the bins:

VHLD*type_mHIST* *hist_base[hist_agen][V2]*, **V0**, **RND_SAT**: *rnd_sat*

The bins are then incremented with normal VADD.

```
VADD V0, V4, V0
```

Results are stored back to the histogram memory with a special histogram store, VHST:

VHST*type_mHIST* **V0**, *hist_base[hist_agen][V2]*

Base and agen are supposed to be consistent between VHLD and VHST; otherwise, the outcome is undetermined.

Both signed and unsigned types are supported in data load, weight load, histogram load/store, to support unsigned histogram as well as weighted histogram with positive and negative weights.

Parameters for histogram are extracted from the instructions:

- Input data type is from VLD V2
- Input data distribution is from VLD V2, with SIMD units 0..num_par_hist-1 used for indexing histogram. NPT, 1PT, DS2, US2 distribution options are supported.
- Optional weight type is from VLD V4.
- Weight distribution behaves like data distribution, i.e., SIMD units 0..num_par_hist-1 used for incrementing parallel histogram bins
- Histogram data type is from VHLD and VHST, and the two instructions must be consistent in the data type, otherwise the outcome is indeterminate.

- `rnd_sat` in VHLD specifies round/truncate mode and how many bits to round off data before indexing the histogram, and also saturation mode and bound. This field is 5-bit (like VST and VTLD), so only P0..P31 is allowed.

The histogram command basically takes the data array, and processes `num_par_hist` data points at a time by assuming that many sets of parallel histogram bin storage. Each data value is rounded, saturated to generate a bin index. The address bin storage elements (which can be byte, halfword, or word) is then incremented by 1 or the weight, saturated to min/max values of that type, signed/unsigned byte/halfword/word:

- For unsigned byte, bin data is saturated to [0, 255].
- For signed byte, bin data is saturated to [-128, 127].
- For unsigned halfword, bin data is saturated to [0, 65535].
- For signed halfword, bin data is saturated to [-32768, 32767].
- For unsigned word, bin data is saturated to [0, 0xFFFF FFFF].
- For signed word, bin data is saturated to [-0x8000 0000, 0x7FFF FFFF].

There are restrictions on the weight data type (as indicated on the VLD into V4):

- Its signed/unsigned designation must agree with the histogram bin (as indicated in VHLD, VHST).
- Its size is limited to byte and halfword, and must be no bigger size than the histogram bin. Thus, for byte sized bins, only byte-sized weights are possible. For halfword or word sized bins, byte or halfword sized weights are possible.

C representation of histogram processing for a single histogram is as follows.

```
for (i=0; i<num_data; i++)
{
    data = data_base[i];
    bin = saturate(round(data));
    hist[bin]++;
}
```

Weighted histogram has the following C representation:

```
for (i=0; i<num_data; i++)
{
    data = data_base[i];
    bin = saturate(round(data));
    hist[bin] += weight[i];
}
```

Histogram organization in memory depends on histogram type and `num_par_hist`. The N physical banks of 32-bit memory is partitioned into `num_par_hist` logical banks, and each parallel histogram is organized inside its own bank, as with parallel lookup tables (see [Figure 8-66](#)).

The histogram command does not pre-initialize the histogram bin storage. The histogram command also does not sum up the parallel sets of storage into a single set; this is performed as a post-processing step.

Histogram operation takes 2M/P cycles plus some per-command overhead to process M data items with P parallel histograms (P = 1, 2, 4, or 8). As P parallel histograms takes P times the storage of a single histogram, it is a tradeoff of memory size and performance.

An example of histogram operation is:

```
; single histogram, byte data, short histogram, round down 2 bits, 33 bins
; rounding mode, shift, saturation bound coded in P7 using scalar instructions
```

```
VLOOP          HIST, CL#: cmd_len, PL#: param_len
VINITHU_ONCE   P1, V4                               ; initialize V4 = 1
VLDBU_NPT      data_base[A0], V2                    ; load data to V2
VHLDHU_1HIST   hist_base[A1][V2], V0, RND_SAT: P7 ; load hist entry into V0
VADD           V0, V4, V0                            ; increment entry
VHSTH_1HIST    V0, hist_base[A1][V2]                ; store histogram entry
```

An example of weighted histogram operation is:

```
; single weighted histogram, byte data, byte weight, short histogram,
; round down 2 bits, 33 bins
; rounding mode, shift, saturation bound coded in P7 using scalar instructions
```

```
VLOOP          HIST, CL#: cmd_len, PL#: param_len
VLDBU_NPT     data_base[A0], V2          ; load data to V2
VLDBU_NPT     weight_base[A2], V4       ; load weights to V4
VHLDHU_1HIST  hist_base[A1][V2], V0, RND_SAT: P7 ; load hist entry into V0
VADD          V0, V4, V0                ; increment entry by weights
VHSTH_1HIST   V0, hist_base[A1][V2]    ; store histogram entry
```

Table lookup and histogram loops are limited to use designated vector register and address generator resources as shown in [Table 8-359](#).

Table 8-359. Table Lookup and Histogram Hardware Resources

Loop type	Input/outputstream	Address generator	Vector register
table lookup	data	A0	V2
	table	A1	V0
	output	A2	V0
load with expansion	flag	A0	V2
	data	n/a	V0
	output	A2	V0
histogram	data	A0	V2
	histogram	A1	V0
	weight	A2	V4

8.3.5.5.9 Circular Buffer Addressing Support

In certain applications, it is desirable to maintain circular buffers for input data and intermediate results. Thus, circular buffer addressing is supported in VCOP.

- Support circular buffer in VLD and VST instructions in compute loops, table lookup loops, and histogram loops. No circular buffer in VTLD (table load) and VHLD/VHST (histogram bin load/store).
- Support is in pointer increment arithmetic, so no load or store in any iteration should straddle the circular buffer boundary.
- Support only 2's power buffer size from 1Kbytes, aligned to the size. For example, 1KB circular buffer can only start/end at 1KB alignment of the memory map.
- Support is in all memory regions.

Circular buffer addressing option is encoded in the `circ_buf` field taking up bits 23..20 of base address:

- 0: no circular buffer addressing
- 1: circular buffer size 1K bytes
- 2: circular buffer size 2K bytes
- 3: circular buffer size 4K bytes
- 4: circular buffer size 8K bytes
- 5: circular buffer size 16K bytes
- 6: circular buffer size 32K bytes
- 7~15: reserved

The base address does not need to be aligned to the circular buffer size, in the above example's case, 0x400. To avoid any single load/store straddle the circular buffer boundary, the base address and the pointer increments must all be aligned to the access size of each iteration.

For example, when loading N data points of halfword data, where N = 8. Access size = 16, so the base address and any pointer increment must be aligned to multiples of 16.

Hardware adjusts the memory address for circular buffering by this process:

```

circ_buf = (base >> 20) & 0xF;           // extract circ_buf
mask = (0x200 << circ_buf) - 1;         // mask = size of buffer - 1
cbuf = (base & 0xFFFFF) & ~mask;        // find base addr of buffer
addr = cbuf + (base + agen) & mask;      // add offset from base of buffer

```

For example, base = 0x10420, agen = 0xFF0.

1. Extract `circ_buf` field by `circ_buf = (base >> 20) & 0xF = 1`, indicating 1KB circular buffer size.
2. Set `mask = (0x200 << 1) - 1 = 0x3FF`, forming the bit mask that defines the circular addressing bits versus linear, non-circular bits.
3. Get rid of the `circ_buf` field by ANDing base with 0xFFFFF, then zero out the circular addressing bits by ANDing with the complement of mask, to get `cbuf = 0x400`, so the circular buffer is 0x400 ~ 0x7FF.
4. Next, add the address generator value to the base address, and AND with mask to find offset from the `cbuf` base. `(base + agen) & mask = (0x10420 + 0xFF0) & 0x3FF = 0x11410 & 0x3FF = 0x10`.
5. Finally, add the offset 0x10 to the circular buffer base 0x400 to get the final address, 0x410.

The `agen` is allowed to go over the circular buffer many times over to wrap back inside, and that `agen` can even go backward to wrap from the beginning to the end of the buffer.

8.3.5.5.10 Load/Store Address Alignment Constraints

Load/store pointer alignment constraints are summarized in [Table 8-360](#), for data load/store as well as table and histogram load/store, for various data types.

Table 8-360. Load and Store Address Alignment Constraints

Type of load/store and distribution	Byte type	halfword type	Word type
VLD_NPT	any	any	word-aligned
VLD_1PT	any	any	any
VLD_CIRC2	any	any	any
VLD_DS2	any	halfword-aligned	not supported
VLD_US2	any	any	any
VLD_DINTRLV	any	word-aligned	not supported
VLD_CUST_Pi	any	any	word-aligned
VLD_EXP	any	halfword-aligned	word-aligned
VST_NPT	any	halfword-aligned	word-aligned
VST_1PT	any	halfword-aligned	word-aligned
VST_DS2	any	halfword-aligned	word-aligned
VST_INTRLV	any	word-aligned	not supported
VST_OFFST_NP1	any	halfword-aligned	word-aligned
VST_COLLAT	any	halfword-aligned	word-aligned
VST_DDA	any	halfword-aligned	word-aligned
VST_SKIP	any	halfword-aligned	not supported
VTLD_1TBL_1PT	any	halfword-aligned	word-aligned
VTLD_mTBL_nPT (other than 1TBL_1PT)	32-byte-aligned	32-byte-aligned	32-byte-aligned
VHLD_mHIST	32-byte-aligned	32-byte-aligned	32-byte-aligned
VHST_mHIST	32-byte-aligned	32-byte-aligned	32-byte-aligned

The rationale is:

- For data load, in general any alignment is supported. Exception: When software loads 32 bytes, the pointer needs to be word-aligned.
- For data store, in general any alignment is supported for byte, halfword alignment for halfword, and word-alignment for word. Exception: When 32 or 64 bytes is stored, the value needs to be word-aligned. In case of LDH_DS2, the pointer must be 16-bit aligned.
- For table load with one table, 1-point lookup, the table base pointer can be of any alignment for byte, halfword alignment for halfword, and word-alignment for word.
- For table load with other configurations, only a 32-byte aligned table base is supported.
- Table store is really data store with 1, 2, 4, or 8 data points. The same alignment is supported as a data store, i.e., any alignment for byte, halfword alignment for halfword, and word-alignment for word.
- For histogram load/store, the histogram base pointer must be 32-byte aligned.

8.3.5.6 Load/Store Buffer and Scheduling

There is load data buffer associated with each VLD instruction in the loop to reduce memory reads and resulting contention and slow-down.

- Size of the buffer is 32 bytes, and is filled with 8 32-bit words on word alignment.
- When the requested data is not contained in the buffer (completely or partially), VCOP reads another 8 32-bit words from the first requested word.
- There is no sharing of data among separate load data buffers.

There is one common store data buffer, basically a shadow copy of all vector registers, for all the VST instructions in the loop to skew memory write timing to reduce memory contentions and resulting slow-down.

- The store data buffer is 16 × 8 × 40-bit in size.
- Vector registers are copied to the store data buffer at the end of i4 iteration, when there is any store to be performed for that iteration. In case stores are not all completed then, load and execution stages are stalled, until all stores are completed.
- Write data from multiple iterations of the same store instruction are not combined. For example, STB_NPT_ALWS causes a memory store of 8 bytes in each iteration.
- Write data from multiple stores of the loop, same iteration, are not combined.

Memory loads and stores are arbitrated for each memory port. There are three memory ports:

- WBUF: Dedicated to WBUF
- IBUFL: For IBULA and IBUFLB
- IBUFH: For IBUFHA and IBUFHB

Load store priorities are: force store > load > store. Force store is issued when the load and operation stages are stalled to free up the store stage so the hardware can advance to the next iteration. Other than force store, load has priority over normal store.

Example 8-9. 3-Tap Horizontal Filtering, Byte Type

VLDL_DINTRLV	Pdata[a0], V0	; data, starts from 0x10000 (IBUFLA)
VLDL_IPT	Pcoef[a1], V2	; coef, starts from 0x0 (WBUF)
VMADD	V0, V2, V4, V4	
VMADD	V1, V2, V5, V5	
VSTB_INTRLV	V4, Pout[a2], RND_SAT: rnd_sat_param	; output, start from 0x10400 (IBUFLA)

Table 8-361. Load and Store Buffering Example, Byte-Type Horizontal Filter

Cycle	LD stage	OP stage	ST stage
0	iter 0 LD0 need 0x10000..0x1000F, read IBUFLA LD0_buf = {0x10000..0x1001F} LD2 need 0x0, read WBUF LD2_buf = {0x0..0x1F}		
1	iter 1 LD0 need 0x10001..0x10010, from LD0_buf LD2 need 0x1, from LD2_buf	iter 0 MADD MADD	
2	iter 2 LD0 need 0x10002..0x10011, from LD0_buf LD2 need 0x2, from LD2_buf	iter 1 MADD MADD	iter 0
3	iter 3 LD0 need 0x10010..0x1001F, from LD0_buf LD2 need 0x0, from LD2_buf	iter 2 MADD MADD	iter 1
4	iter 4 LD0 need 0x10011..0x10020, read IBUFLA LD0_buf = {0x10010..0x1002F} LD2 need 0x1, from LD2_buf	iter 3 MADD MADD	iter 2 ST0 store 0x10400..0x1040F queue the store

Table 8-361. Load and Store Buffering Example, Byte-Type Horizontal Filter (continued)

Cycle	LD stage	OP stage	ST stage
5	iter 5 LD0 need 0x10012..0x10021, from LD0_buf LD2 need 0x2, from LD2_buf	iter 4 MADD MADD	iter 3 store IBUFLA
6	iter 6 LD0 need 0x10020..0x1002F, from LD0_buf LD2 need 0x0, from LD2_buf	iter 5 MADD MADD	iter 4
7	iter 7 LD0 need 0x10021..0x10030, read IBUFLA LD0_buf = {0x10020..0x1003F} LD2 need 0x1, from LD2_buf	iter 6 MADD MADD	iter 5 ST0 store 0x10410..0x1041F queue the store

Here LDB_DINTRLV is used to read 16 data points, to operate on 16 outputs in parallel. The hardware issues memory reads for iteration 0, 4, 7, etc, is able to supply data for subsequent hold data read in for subsequent LD; on average there is 1 read every 3 cycles. For coefficient, since only 3 bytes is used, just one read in iteration 0 is sufficient to supply data for the whole loop. Output is produced in iteration 2, 5, etc, and the store buffer delays the write until there is no read traction, avoiding read/write contention and slowdown.

Due to memory read/write timing, delayed slot in operation, and round/saturate feature in the store stage, the skew between load, operation, and store stages is more than what is shown in [Table 8-361](#), but for calculating steady-state performance, simplified analysis like this is sufficient.

Example 8-10. Horizontal Filtering, Short Type

VLDH_NPT	Pdata0[a0], V0	; data, start from 0x10000 (IBUFLA)
VLDH_NPT	Pdata1[a0], V2	; data next row, start from 0x10080 (IBUFLA)
VLDH_1PT	Pcoef[a1], V4	; coef, start from 0x0 (WBUF)
VMADD	V0, V4, V6, V6	
	VMADD	V2, V4, V7, V7
VSTH_NPT	V6, Pout0[a2], RND_SAT: rnd_sat_param	; start from 0x10400 (IBUFLA)
VSTH_NPT	V7, Pout1[a2], RND_SAT: rnd_sat_param	; start from 0x10480 (IBUFLA)

Software cannot issue VLDH_DINTRLV on odd halfwords, so use two LDH_NPT.

Table 8-362. Load and Store Buffering Example, Short-Type Horizontal Filter

Cycle	LD stage	OP stage	ST stage
0	iter 0 LD0 need 0x10000..0x1000F, read IBUFLA LD0_buf = {0x10000..0x1001F} LD1 need 0x10080 .. 0x1008F, stalled LD2 need 0..1, read WBUF LD2_buf = {0x0..0x1F}		
1	iter 0 LD1 read IBUFLA LD1_buf = {0x10080..0x1009F}		
2	iter 1 LD0 need 0x10002..0x10011, from LD0_buf LD1 need 0x10082..0x10091, from LD1_buf LD2 need 2..3, from LD2_buf	iter 0 MADD MADD	
3	iter 2 LD0 need 0x10004..0x10013, from LD0_buf LD1 need 0x10084..0x10093, from LD1_buf LD2 need 4..5, from LD2_buf	iter 1 MADD MADD	iter 0
4	iter 3 LD0 need 0x10010..0x1001F, from LD0_buf LD1 need 0x10090 .. 0x1009F, from LD1_buf LD2 need 0..1, from LD2_buf	iter 2 MADD MADD	iter 1

Table 8-362. Load and Store Buffering Example, Short-Type Horizontal Filter (continued)

Cycle	LD stage	OP stage	ST stage
5	iter 4 LD0 need 0x10012..0x10021, read IBUFLA LD0_buf = {0x10010..0x1002F} LD1 need 0x10092 .. 0x100A1, stall LD2 need 2..3, from LD2_buf	iter 3 MADD MADD	iter 2 ST0 store 0x10400..0x1040F ST0 queued ST1 store 0x10480..0x1048F ST1 queued
6	iter 4 LD1 read IBUFLA LD1_buf = {0x10090..0x100AF}	stalled	stalled
7	iter 5 LD0 need 0x10014..0x10023, from LD0_buf LD1 need 0x10094..0x100A3, from LD1_buf LD2 need 4..5, from LD2_buf	iter 4 MADD MADD	iter 3 ST0 write IBUFLA
8	iter 6 LD0 need 0x10020..0x1002F, from LD0_buf LD1 need 0x100A0..0x100AF, from LD1_buf LD2 need 0..1, from LD2_buf	iter 5 MADD MADD	iter 4 ST1 write IBUFLA
9	iter 7 LD0 need 0x10022..0x10031, read IBUFLA LD0_buf = {0x20..x3F} LD1 need 0x100A2..0x100B1, stall LD2 need 2..3, from LD2_buf	iter 6	iter 5 ST0 store 0x10410..0x1041F ST0 queued ST1 store 0x10490..0x1049F ST1 queued
10	iter 7 LD1 read IBUFLA LD1_buf = {0x100A0..0x100BF}	stalled	stalled

In this loop, with 2 VLDH_NPT to sustain 16 multiply-accumulates per iteration, the load stage stalled due to memory contention in IBUFL from the 2 loads. The read buffer supplies data for 2 subsequent iterations in steady state, leaving 2 memory-read free cycles every 3 iterations. With output writing back to IBUFL, the store buffer effectively delays the memory writes to use these free memory slots. Each i4 loop of 3 iterations thus takes 4 cycles to complete.

8.3.5.7 VCOP Per-Loop Overhead

For each vector command specifying a loop, several overhead components are present. In general, developers are encouraged to run place into each loop as much processing as possible and run as many iterations as possible to reduce the percentage of time spent on overhead.

Overhead components are:

- Command decode time: it takes 2 cycles per instruction to decode, since scalar core is providing instructions at this rate. Command decode time can be hidden if ARP32 feeds these instructions while VCOP is executing a previous command.
- Parameter fetch time: it takes $9 + \text{ceiling}(\text{num_param}/16)$ cycles to fetch parameter from data memory (WBUF, IBUFL, or IBUFH).
- Execution pipeline ramp up/down time: it takes time to ramp up and down the long pipeline of VCOP. Minimal time for any loop is execution is about 17 cycles, due to the pipeline ramp up/down time.

Figure 8-67 shows a decode-parameter-fetch-execution time line.

Figure 8-67. Example of Operation Delay Slots

- t = 0, ARP32 sends VLOOP, followed by VCOP instructions in the loop, instructions go into FIFO.
- t = 2, VCOP pulls instruction out of FIFO, recognizes VLOOP.
- t = 10 (depend on command length), VCOP pulls last instruction of loop from FIFO.
- t = 10, ARP32 sends next command, starting from VLOOP.
- t = 14, VCOP starts access to parameter memory, 16 parameters/cycle.
- t = 18, ARP32 keeps sending vector commands, until program stream switches to scalar code, or VCOP pre-decode instruction FIFO becomes full (capacity is 64 words).
- t = 23 (14 + 9), VCOP starts to copy parameters into decoded command buffer.
- t = 25 (after parameter copy), VCOP starts executing the loop.
- t = 26 (sync to 250-MHz clock), VCOP pulls instruction out of FIFO, recognizes VLOOP.
- t = 32 (depend on command length), VCOP pulls last instruction of loop from FIFO.
- t = 36 (after prev loop finishes executing), VCOP starts to access parameter memory.

This is for showing the dependency among activities; execution time here is not realistic; it takes minimally 17 cycles to execute any loop, due to the pipeline depth.

8.3.5.8 VCOP Error Handling

Upon detection of erroneous instruction code, parameter, load/store address, or loop in execution exceeding programmed max iteration count, VCOP signals the error by generating an interrupt and registering the error source in the MMR [VCOP_ERROR](#). Refer to register manual for details.

Upon detection of error, VCOP:

1. Terminates current loop, leaving vloop_ptr, param_ptr, loop variables i0, i1, i2, i3, i4 in MMR.
2. Parses and clears vector instructions until encountering VWDONE.
3. Issues interrupt, assert vec_done = 1, deassert vec_rdy = 0 to block subsequent vector instructions.
4. Upon [VCOP_ERROR](#) status being cleared (by writing 1s to clear bits 10:0), VCOP becomes idle (assert [VCOP_STATUS](#)[2]VEC_RDY = 1) and ready to resume processing.
5. Alternatively, VCOP can be reset to resume processing.

Depending on the EVE-level memory switch setting, VCOP's access of the data memory space may be deemed invalid by the memory switch. When this happens, the memory switch signals VCOP to enter error handling state, as described above. VCOP does not send an error interrupt, as the memory switch is doing that (for invalid access from VCOP or from other masters).

8.3.5.9 Vector Operation Details

8.3.5.9.1 VABS

Assembly syntax: **VABS** *src1, dst*
 Operation: Absolute value
 Classification: 1-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = abs(src1);`

8.3.5.9.2 VABSDIF

Assembly syntax: **VABSDIF** *src1, src2, dst*
 Operation: absolute-difference
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = abs(src1 – src2);`

8.3.5.9.3 VADD

Assembly syntax: **VADD** *src1, src2, dst*
 Operation: addition
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = src1 + src2;`

8.3.5.9.4 VADDH

Assembly syntax: **VADDH** *src1, src2, dst*
 Operation: Add high
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = src1 + (src2 >> 32);`

8.3.5.9.5 VADDSUB

Assembly syntax: VADDSUB src1/dst1, src2/dst2
 Operation: Add-subtract
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: dst1 = src1 + src2;
 dst2 = src1 – src2;

8.3.5.9.6 VADD3

Assembly syntax: **VADD3** src1, src2, src3, dst (dst same as src3)
 Operation: Add 3 items,
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: dst = src1 + src2 + src3;

8.3.5.9.7 VADIF3

Assembly syntax: **VADIF3** src1, src2, src3, dst (dst same as src3)
 Operation: Add difference
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: dst = src1 – src2 + src3;

8.3.5.9.8 VAND

Assembly syntax: **VAND** src1, src2, dst
 Operation: Bitwise and
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: dst = src1 & src2;

8.3.5.9.9 VANDN

Assembly syntax: **VANDN** src1, src2, dst
 Operation: Bitwise and-not
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: dst = src1 & ~src2;

8.3.5.9.10 VAND3

Assembly syntax: **VAND3** *src1, src2, src3, dst* (dst same as src3)
 Operation: Bitwise-and 3 items
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: `dst3 = src1 & src2 & src3;`

Using VAND3 accelerates a morphological erosion operation.

8.3.5.9.11 VBINLOG

Assembly syntax: **VBINLOG** *src1, dst*
 Operation: Binary log
 Classification: 1-input 1-output
 Bit width: 32-bit
 Delay slot: one
 C statement: As follows

VBINLOG computes an approximate binary log, by detecting the left-most 1 bit in the input, encoding the bit position in bits 31..28, and left-justifying the following input bits in bits 27..0. The detected position of bit 31 is encoded as 15 (bit position minus 16), bit 30 as 14, and so on, and bit 17 as 1. If the left-most 1 bit is not found in bits 31..17, 0 is coded.

The VBINLOG operation is a non-standard floating point representation. Say a 32-bit integer $x = 2^{\text{exp}} * (1 + \text{frac}/(2^{28}))$, where exp and frac are integers. If $(\text{exp} \geq 16)$, $\text{binlog}(x) = (\text{exp} - 16) * (2^{28}) + \text{frac}$, concatenating the 4-bit adjusted exponent, $\text{exp} - 16$, with the 28-bit fraction. Otherwise, the representation is subnormal, leaving 0 in the exponent and bits 16..0 of input left-justified in the fraction part of output, bits 27..0.

For example, the number 0x0700_0000 has leading 1 in bit 26, so the bit position is coded as $26 - 16 = 10 = 0xA$. The subsequent bits, two 1s immediately following the leading 1, left-justified in 28 bits or 7 hex digits, is 0xC00_0000. Thus the VBINLOG outcome of the number is 0xAC00_0000.

For a subnormal example, the number 0x8000 $< 2^{16}$ (is half of that), so its VBINLOG outcome is 0x0400_0000.

Figure 8-68. Binlog Function

input																binlog output

0	0	0	0	0	0	0	0	0	0	0	0	1	b18	b17	b16	b15	...	0	0	1	1	b18	b17	...	0		
0	0	0	0	0	0	0	0	0	0	0	0	0	1	b17	b16	b15	...	0	0	1	0	b17	b16	...	0		
0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	b16	b15	...	0	0	0	1	b16	b15	...	0		
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	b16	b15	...	0	0	0	0	b16	b15	...	0		

Input of VBINLOG is 32-bit, and so is the outcome, not 40-bit. VLMBD supports full 40-bit input range leading bit detection. VBINLOG is useful in compressing dynamic range and preserving precision. VBINLOG followed by table lookup can be used to produce the reciprocal of a number.

8.3.5.9.12 VBITC

Assembly syntax: **VBIT** *src1, dst*
 Operation: Bit count
 Classification: 1-input 1-output
 Bit width: 32-bit
 Delay slot: one
 C statement: As follows

Count number of “1” bits in *src1*[31:0].

8.3.5.9.13 VBITDI

Assembly syntax: **VBITDI** *src1, dst1, dst2*
 Operation: Bit deinterleave
 Classification: 1-input 2-output
 Bit width: 32-bit
 Delay slot: 0
 C statement: As follows

Bit deinterleave is basically the inverse of bit interleave (VBITI).

For example,

```
src1 = 0x523(0000_0000_0000_0000_0000_1001_0010_0011)
```

Results in:

```
dst1 = 0x25 (0000_0000_0010_0101),  
dst2 = 0x11(0000_0000_0001_0001)
```

8.3.5.9.14 VBITI

Assembly syntax: **VBITI** *src1, src2, dst*
 Operation: Bit interleave
 Classification: 2-input 1-output
 Bit width: 32-bit
 Delay slot: one
 C statement: As follows

Bit interleave 16 LSBs of *src1* and *src2* (each), and write to *dst*.

For example,

```
src1 = 0x25 (0000_0000_0010_0101)  
src2 = 0x11(0000_0000_0001_0001)
```

Results in:

```
dst = 0x523(0000_0000_0000_0000_0000_1001_0010_0011)
```

8.3.5.9.15 **VBITPK**

Assembly syntax: **VBITPK** *src1, src2, dst*
 Operation: Bit-pack
 Classification: 2-input 1-output
 Bit width: 33-bit
 Delay slot: one
 C statement: As follows

Pack boolean ($src1[i] \geq src2[i]$) into bits in $dst[0]$, and broadcast $dst[0]$ to all SIMD lanes so that $dst[j] = dst[0]$, $1 \leq j \leq NSIMD$.

VBITPK is useful in accessing bit-packed data (binary images).

8.3.5.9.16 **VBITR**

Assembly syntax: **VBITR** *src1, dst*
 Operation: Bit reverse
 Classification: 1-input 1-output
 Bit width: 32-bit
 Delay slot: one
 C statement: As follows

Reverse bits in $src1[31:0]$ and write to dst .

8.3.5.9.17 **VBITTR**

Assembly syntax: **VBITTR** *src1, dst*
 Operation: Bit transpose
 Classification: 1-input 1-output
 Bit width: NSIMD-bit
 Delay slot: one

VBITTR, bit transpose, also called corner turn, takes $N \times N$ bits in the source, from N LSBs of each of the N registers, and transpose them. Here is an example:

Input:				Output:							
		Bit position						Bit position			
<u>Lane</u>	<u>Value</u>	<u>0</u>	<u>1</u>	<u>2</u>	<u>3</u>	<u>Lane</u>	<u>Value</u>	<u>0</u>	<u>1</u>	<u>2</u>	<u>3</u>
0	1	1	0	0	0	0	5	1	0	1	0
1	2	0	1	0	0	1	6	0	1	1	0
2	3	1	1	0	0	2	8	0	0	0	1
3	4	0	0	1	0	3	0	0	0	0	0

8.3.5.9.18 **VBITUNPK**

Assembly syntax: **VBITUNPK** *src1, src2, dst*
 Operation: Bit-unpack
 Classification: 2-input 1-output
 Bit width: 33-bit
 Delay slot: one
 C statement: As follows

Unpack bits in *src1[0]*. Set *dst[i] = src2[i]* if the unpacked bit to lane *i* is 1, otherwise *dst[i] = 0*.

8.3.5.9.19 **VCMOV**

Assembly syntax: **VCMOV** *cond, src1[, src2|dst]*
 Operation: Conditional move
 Classification: special
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

cond = {I1234_ZERO, I234_ZERO, I34_ZERO, LAST_I4_ZERO, LAST_I34, LAST_I234, LAST_I1234}.

Move *src1* to *dst* in the iterations designated by *cond*. This is parallel move within each SIMD lane; *dst[i] = src1[i]* when condition is true. Otherwise, *dst[i] = src2[i]*. By always writing to the *dst* register, *dst* register does not need to be {V0, V1, V2, V3} (see [Section 8.3.5.5.6](#) for details on the store-without-being destination register constraint).

8.3.5.9.20 **VCMPPEQ**

Assembly syntax: **VCMPPEQ***src1, src2, dst*
 Operation: Compare equal
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: *dst = (src1 == src2) ? 1 : 0;*

8.3.5.9.21 **VCMPGE**

Assembly syntax: **VCMPGE** *src1, src2, dst*
 Operation: Compare greater-than-or-equal
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: *dst = (src1 >= src2) ? 1 : 0;*

8.3.5.9.22 **VCMPGT**

Assembly syntax: **VCMPGT** *src1, src2, dst*
 Operation: Compare greater-than
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = (src1 > src2) ? 1 : 0;`

8.3.5.9.23 **VDINTRLV**

Assembly syntax: **VDINTRLV** *{src1|dst1}, {src2|dst2}*
 Operation: Deinterleave
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VDINTRLV is basically the inverse of VINTRLV.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst2[0] = src1[1];
dst1[1] = src1[2];
dst2[1] = src1[3];
dst1[2] = src1[4];
dst2[2] = src1[5];
dst1[3] = src1[6];
dst2[3] = src1[7];
dst1[4] = src2[0];
dst2[4] = src2[1];
dst1[5] = src2[2];
dst2[5] = src2[3];
dst1[6] = src2[4];
dst2[6] = src2[5];
dst1[7] = src2[6];
dst2[7] = src2[7];
  
```

8.3.5.9.24 **VDINTRLV2**

Assembly syntax: **VDINTRLV2** {*src1|dst1*}, {*src2|dst2*}
 Operation: Deinterleave with 2-element frequency
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VDINTRLV2 is basically the inverse of VINTRLV2.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst1[1] = src1[1];
dst2[0] = src1[2];
dst2[1] = src1[3];
dst1[2] = src1[4];
dst1[3] = src1[5];
dst2[2] = src1[6];
dst2[3] = src1[7];
dst1[4] = src2[0];
dst1[5] = src2[1];
dst2[4] = src2[2];
dst2[5] = src2[3];
dst1[6] = src2[4];
dst1[7] = src2[5];
dst2[6] = src2[6];
dst2[7] = src2[7];
  
```

8.3.5.9.25 **VEXITNZ**

Assembly syntax: **VEXITNZ** *level*, *src1*
 Operation: Exit upon non-zero
 Classification: special
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VEXITNZ is for early termination of VLOOP or in the repeat-loop level. The designated *src1* register's 0th way is examined every time the instruction executes, and if it is not zero, the hardware terminates either at VLOOP level or at VRPT level, as indicated by the level parameter.

Parameter *src1* is examined at the time the instruction executes, and an exit/no-exit decision is made. However, any exit/no-exit action is not taken immediately. For VEXITNZ VLOOP, subsequent instructions in the same iteration, remaining operations and all the stores, are executed, then the loop terminates. For VEXITNZ VRPT; all subsequent instructions in the same loop are executed, including the rest of the iteration, and all remaining iterations until *i1*, *i2*, *i3*, *i4* all run to respective end counts, then the repeated loop terminates.

There can only be one VEXITNZ in each vector command; no mixing of VEXITNZ VLOOP and VEXITNZ VRPT. When the vector command is not repeated (*RPT_END* = 0), VEXITNZ VRPT behaves like VEXITNZ VLOOP.

8.3.5.9.26 VINTRLV

Assembly syntax: **VINTRLV** {src1|dst1}, {src2|dst2}
 Operation: Interleave
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VINTRLV is basically interleaving among SIMD lanes.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst1[1] = src2[0];
dst1[2] = src1[1];
dst1[3] = src2[1];
dst1[4] = src1[2];
dst1[5] = src2[2];
dst1[6] = src1[3];
dst1[7] = src2[3];
dst2[0] = src1[4];
dst2[1] = src2[4];
dst2[2] = src1[5];
dst2[3] = src2[5];
dst2[4] = src1[6];
dst2[5] = src2[6];
dst2[6] = src1[7];
dst2[7] = src2[7];
  
```

8.3.5.9.27 VINTRLV2

Assembly syntax: **VINTRLV2** {src1|dst1}, {src2|dst2}
 Operation: Interleave with 2-element frequency
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VINTRLV is basically interleaving among SIMD lanes.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst1[1] = src1[1];
dst1[2] = src2[0];
dst1[3] = src2[1];
dst1[4] = src1[2];
dst1[5] = src1[3];
dst1[6] = src2[2];
dst1[7] = src2[3];
dst2[0] = src1[4];
dst2[1] = src1[5];
dst2[2] = src2[4];
dst2[3] = src2[5];
dst2[4] = src1[6];
dst2[5] = src1[7];
dst2[6] = src2[6];
dst2[7] = src2[7];
  
```

8.3.5.9.28 **VINTRLV4**

Assembly syntax: **VINTRLV4** {*src1|dst1*}, {*src2|dst2*}
 Operation: Interleave with 4-element frequency
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VINTRLV is basically interleaving among SIMD lanes.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst1[1] = src1[1];
dst1[2] = src1[2];
dst1[3] = src1[3];
dst1[4] = src2[0];
dst1[5] = src2[1];
dst1[6] = src2[2];
dst1[7] = src2[3];
dst2[0] = src1[4];
dst2[1] = src1[5];
dst2[2] = src1[6];
dst2[3] = src1[7];
dst2[4] = src2[4];
dst2[5] = src2[5];
dst2[6] = src2[6];
dst2[7] = src2[7];
  
```

8.3.5.9.29 **VLMBD**

Assembly syntax: **VLMBD** *src1, src2, dst*
 Operation: Left-most bit detect
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: As follows

Depending on *src2* being zero or not, VLMBD searches for 0 or 1 in *src1*, starting from bit 39. Bit position where the first 0 or 1 occurs is returned, and -1 is returned if it's not found.

8.3.5.9.30 VMADD

Assembly syntax: **VMADD** *src1, src2, src3, dst, RND: rnd_param* (dst same as src3)
 Operation: Multiply-add
 Classification: 3-input 1-output
 Bit width: 17-bit src1/src2, 40-bit src3/dst
 Delay slot: 2 delay from src1/src2, 1 delay from src3
 C statement: $dst = src3 + \text{round_or_shift}(src1 * src2, rnd_param)$

The RND field specifies a parameter, in which additional fields are read to support built-in round/shift feature in the operation:

Figure 8-69. VMPY, VMADD and VMSUB Rounding Parameters

Table 8-363. Parameter Indexed by rnd_param Field Descriptions

Bits	Name	Description
15-7	Reserved	
6-5	rnd_mode	Sets rounding mode: 0 No rounding 1 Round 2 Truncate 3 Left-shift
4-0	rnd_shift	Number of bits to round/shift, limited to: {8 15 16} Round/truncate 1 Left-shift

When rnd_mode = round or truncate, $src1 * src2$ is rounded down before the addition or subtraction.
 When rnd_mode = left-shift, $src1 * src2$ is shifted up before the addition or subtraction. Note the restriction on the number of bits to shift.

8.3.5.9.31 VMAX

Assembly syntax: **VMAX** *src1, src2, dst*
 Operation: Maximum
 Classification: 2-input 1-output
 Bit width: 33-bit
 Delay slot: no
 C statement: $dst = (src1 > src2) ? src1 : src2;$

8.3.5.9.32 **VMAXSETF**

Assembly syntax: **VMAXSETF** *src1*, {*src2*|*dst1*}, *dst2*
 Operation: Maximum and set flag
 Classification: 2-input 2-output
 Bit width: 33-bit
 Delay slot: no
 C statement: $dst1 = \max(src1, src2); dst2 = (src1 > src2) ? 1 : 0$

8.3.5.9.33 **VMIN**

Assembly syntax: **VMIN** *src1*, *src2*, *dst*
 Operation: Minimum
 Classification: 2-input 1-output
 Bit width: 33-bit
 Delay slot: no
 C statement: $dst = (src1 < src2) ? src1 : src2;$

8.3.5.9.34 **VMINSETF**

Assembly syntax: **VMINSETF** *src1*, {*src2*|*dst1*}, *dst2*
 Operation: Minimum and set flag
 Classification: 2-input 2-output
 Bit width: 33-bit
 Delay slot:
 C statement: $dst1 = \min(src1, src2);$
 $dst2 = (src1 < src2) ? 1 : 0;$

8.3.5.9.35 **VMPY**

Assembly syntax: **VMPY** *src1*, *src2*, *dst*, **RND**: *rnd_param*
 Operation: multiply
 Classification: 2-input 1-output
 Bit width: 17-bit input, 40-bit output
 Delay slot: one
 C statement: $dst = \text{round_or_shift}(src1 * src2, rnd_param);$

See [VMADD](#) for the RND field.

8.3.5.9.36 **VMSUB**

Assembly syntax: **VMSUB** *src1, src2, src3, dst, RND: rnd_param* (dst same as src3)
 Operation: Multiply-subtract
 Classification: 3-input 1-output
 Bit width: 17-bit src1/src2, 40-bit src3/dst
 Delay slot: 2 delay from src1/src2, 1 delay from src3
 C statement: `dst = src3 - round_or_shift(src1 * src2, rnd_param);`

See [VMADD](#) for the RND field.

8.3.5.9.37 **VNOP**

Assembly syntax: **VNOP**
 Operation: no operation
 Classification: n/a
 Bit width: n/a
 Delay slot: no
 C statement: n/a

NOP is used to pad the two operations per clock cycle operation pipeline, so the next operation is mapped to functional unit 1. This is used to align data dependency to within functional unit 0 or 1, to avoid idle cycles being inserted by hardware.

8.3.5.9.38 **VNOT**

Assembly syntax: **VNOT** *src1, dst*
 Operation: Bitwise complement
 Classification: 1-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = ~src1;`

8.3.5.9.39 **VOR**

Assembly syntax: **VOR** *src1, src2, dst*
 Operation: Bitwise or
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = src1 | src2;`

8.3.5.9.40 VOR3

Assembly syntax: **VOR3** *src1, src2, src3, dst* (dst same as src3)
 Operation: Bitwise-or 3 items
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: `dst3 = src1 | src2 | src3;`

Using VOR3 accelerates the morphological dilation operation.

8.3.5.9.41 VRND

Assembly syntax: **VRND** *src1, src2, dst*
 Operation: Round src1 by number of bits expressed in src2
 Classification: 2-input 1-output
 Bit width: 40-bit src1/dst, 5-bit src2, allowing rounding by 0 ~ 31 bits
 Delay slot: one
 C statement: `rnd_add = (src2 > 0) ? (1 << (src2 - 1)) : 0;`
`dst = (src1 + rnd_add) >> src2;`

A half-unit is added before the right-shift. For example, if src2 = 8, `dst = (src1 + 128) >> 8`.

Only src2[4:0] are read, so for example src2 = 40 causes a rounding by 8 bits, since src2[4:0] = 0x08.

8.3.5.9.42 VSAD

Assembly syntax: **VSAD** *src1, src2, src3, dst* (dst same as src3)
 Operation: Sum of absolute difference, `dst = |src1 - src2| + src3`
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: `dst = src3 + abs(src1 - src2);`

8.3.5.9.43 VSEL

Assembly syntax: **VSEL** *src1, src2, src3, dst* (dst same as src3)
 Operation: Select
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = src1 ? src2 : src3;`

8.3.5.9.44 VSHF

Assembly syntax: **VSHF** *src1, src2, dst*
 Operation: Arithmetic shift, shift left when *src2* > 0, shift right by $-src2$ when *src2* < 0
 Classification: 2-input 1-output
 Bit width: 40-bit *src1*/*dst*, 6-bit *src2*, allowing shifting by -32 ~ 31 bits
 Delay slot: no
 C statement: $dst = (src2 \geq 0) ? (src1 \ll src2) : (src1 \gg -src2);$

VSHF is an arithmetic shift, not logic shift, compared to conventional instruction sets that have both options. This is because VCOP performs sign extension in the load stage, and all signed/unsigned 8/16/32-bit operations are carried out with the 40-bit register file.

Only *src2*[5:0] are read, so for example *src2* = 32 causes a right-shift by 32 bits, since *src2*[5:0] = 0x20.

8.3.5.9.45 VSHFOR

Assembly syntax: **VSHFOR** *src1, src2, src3, dst* (*dst* same as *src3*)
 Operation: Shift-or
 Classification: 3-input 1-output
 Bit width: 40-bit *src1*/*src3*, 6-bit *src2*
 Delay slot: one
 C statement: $dst3 = (src2 \geq 0) ? (src3 | (src1 \ll src2)) : (src3 | (src1 \gg -src2));$

See [VSHF](#) for the supported range of *src2*.

8.3.5.9.46 VSHF16

Assembly syntax: **VSHF16** *src1, dst1, dst2*
 Operation: Shift-up 16 bits
 Classification: 1-input 2-output
 Bit width: 33-bit *src1*
 Delay slot: no
 C statement: $dst1 = (src1 \& 0xffff) \ll 16; dst2 = src1 \gg 16;$

Shift up *src1* by 16 bits, producing two destinations to hold the outcome, *dst1* having the lower unsigned 32-bit, and *dst2* having the signed upper portion, sign extended from *src1*[32] to full 40 bits in *dst2*.

VSHF16 is useful for 32 × 32 multiplication.

8.3.5.9.47 VSIGN

Assembly syntax: **VSIGN** *src1, src2, dst*
 Operation: Sign
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst = (src1 == 0) ? 0 : ((src1 > 0) ? src2 : -src2);$

8.3.5.9.48 VSORT2

Assembly syntax: **VSORT2** *src1, src2, dst*
 Operation: Sort two items
 Classification: 2-input 2-output
 Bit width: 33-bit
 Delay slot: no
 C statement: $dst1 = \min(src1, src2);$
 $dst2 = \max(src1, src2);$

8.3.5.9.49 VSUB

Assembly syntax: **VSUB** *src1, src2, dst*
 Operation: Subtraction
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst = src1 - src2;$

8.3.5.9.50 VSWAP

Assembly syntax: **VSWAP** *cond, {src1|dst1}, {src2|dst2}*
 Operation: Conditional swap
 Classification: 3-input 2-output
 Bit width: 1-bit cond, 40-bit src1 & src2
 Delay slot: no
 C statement: $\text{if } (cond \ \& \ 1) \ \text{swap}(src1, src2)$

Only the LSB of the vector register indicated by *cond* is checked. A swap/no-swap decision is made in each SIMD lane using the LSB of *cond* register in the lane.

8.3.5.9.51 VXOR

Assembly syntax: **VXOR** *src1, src2, dst*
 Operation: Bitwise exclusive-or
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst = src1 \wedge src2;$

8.3.6 Debug Support

VCOP supports single stepping, one innermost (i4) iteration per step. Due to the deeply pipelined architecture, instruction-by-instruction single stepping support is not feasible.

Normally VCOP executes load in one stage of the pipeline, and operations and stores in the next stage of the pipeline. In single step mode, only one iteration is executed at a time, so there is no pipelining among iterations. The hardware executes all the loads, then operations and stores, then halts until instructed to continue on the next iteration. The single step operation is controlled via the [VCOP_CTRL](#) register. The operation is enabled by setting [VCOP_CTRL\[0\]STEP_EN](#) to 1. Setting [VCOP_CTRL\[1\]STEP_GO](#) to 1 the engine starts executing i4 iteration.

As outlined in the previous section, `step_en`, `step_go`, `step_rdy` register fields are provided for single stepping control. In addition, VCOP internal state is exported as read-only view as memory-map registers as well.

Interaction of debug driver, scalar core, and VCOP is as follows:

1. Debug driver enables debug mode by setting [VCOP_CTRL\[0\]STEP_EN](#) = 1 and wait for [VCOP_STATUS\[0\]STEP_RDY](#) = 1.
2. Scalar core sends the vector command to be single-stepped the normal fashion.
3. Vector core executes the vector command and stalls at the end of the first i4 iteration and assert [VCOP_STATUS\[0\]STEP_RDY](#).
4. When [VCOP_STATUS\[0\]STEP_RDY](#) = 1, debug driver accesses buffer switch and switch WBUF, IBUFL/H memories to system bus.
5. Debug driver read out the memory contents to refresh on the debugger user interface.
6. Debug driver read out VCOP internal state to refresh on the debugger user interface.
7. Debug driver accesses buffer switch and switch memories to VCOP.
8. Debug driver triggers VCOP to take the next step by writing '1' to `step_go`, and wait for [VCOP_STATUS\[0\]STEP_RDY](#) = 1.
9. Repeat 3 through 8, until completion of the vector command or user input to stop single-stepping.
10. The debug driver disables the debug mode by setting [VCOP_CTRL\[0\]STEP_EN](#) = 0.
11. VCOP and scalar core continue to operate.

Imaging Subsystem

This chapter describes the Imaging Subsystem (ISS) in the device.

Topic	Page
9.1 ISS Overview	2191
9.2 ISS Camera Adapter Layer (CAL)	2251
9.3 ISS Image Signal Processor (ISP)	2350
9.4 ISS Still Image Coprocessor (SIMCOP)	3136

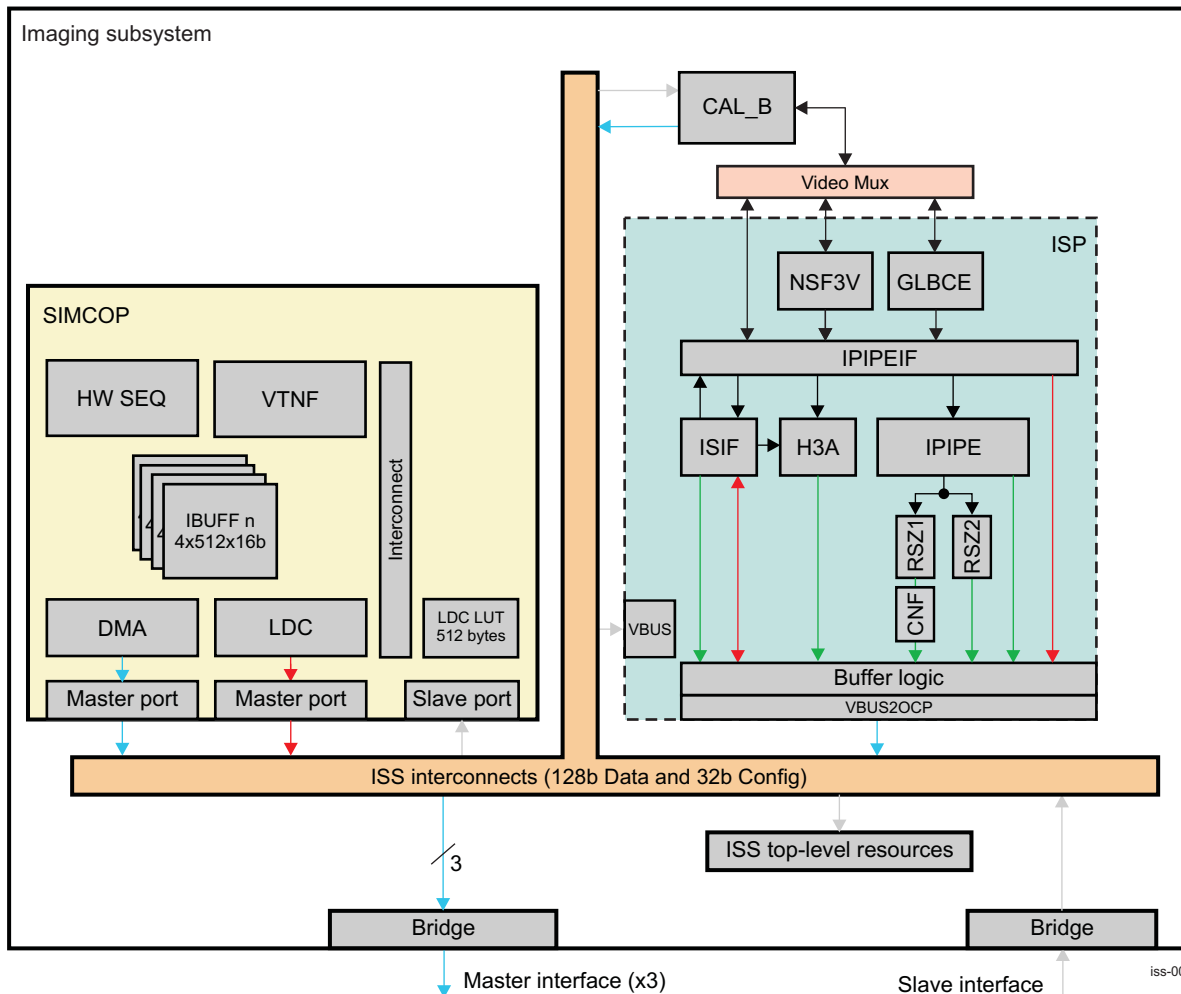

9.1 ISS Overview

The imaging subsystem (ISS) deals with the processing of the pixel data coming from memory (image format encoding and decoding can be done to and from memory). With its subparts, such as interfaces and interconnects, image signal processor (ISP), Camera Adapter Layer (CAL), and still image coprocessor (SIMCOP), the ISS is a key component for the following use cases:

- Machine vision
- Robots with cameras
- Appliances with cameras

Figure 9-1 shows an overview of the ISS.

Figure 9-1. ISS Overview

The direction of the arrows shows the command flow direction from the master (initiator) to the slave (target). The following color conventions are used for the connections:

- Blue: Bidirectional, 128-bit-wide interface data connection.
- Green: Write (ISS → system memory) data connection. Either 64-bit interface, 128-bit interface, or 32-bit MTC (inside ISP).
- Red: Read (system memory to ISS) data connection. 128-bit interface port or 32-bit MTC (inside ISP).
- Gray: 32-bit interface configuration connection.
- Solid black: Video port and camera interface related signals.
- Dotted black: Data flow stall control signal. Used to slow down ISP for memory-to-memory operation.

The ISS is mainly composed of CAL_B, an ISP, and a block-based imaging accelerator (SIMCOP).

The ISS is designed to reach high throughput and low latency with large image sensors. In high-performance mode, the ISP supports a pixel throughput of up to 532 MPix/s.

The ISS targets the following major use cases:

- Video / Preview
 - Up to 1080p60
 - Up to 2x 1080p30
- Stereo Video / Preview
 - Up to 2x 1080p30
- Multi-camera use cases:
 - Up to 4 simultaneous cameras. ISP is time-shared.

NOTE: For a detailed list of features of a certain submodule, see the related subsection.

The ISS offers the following features:

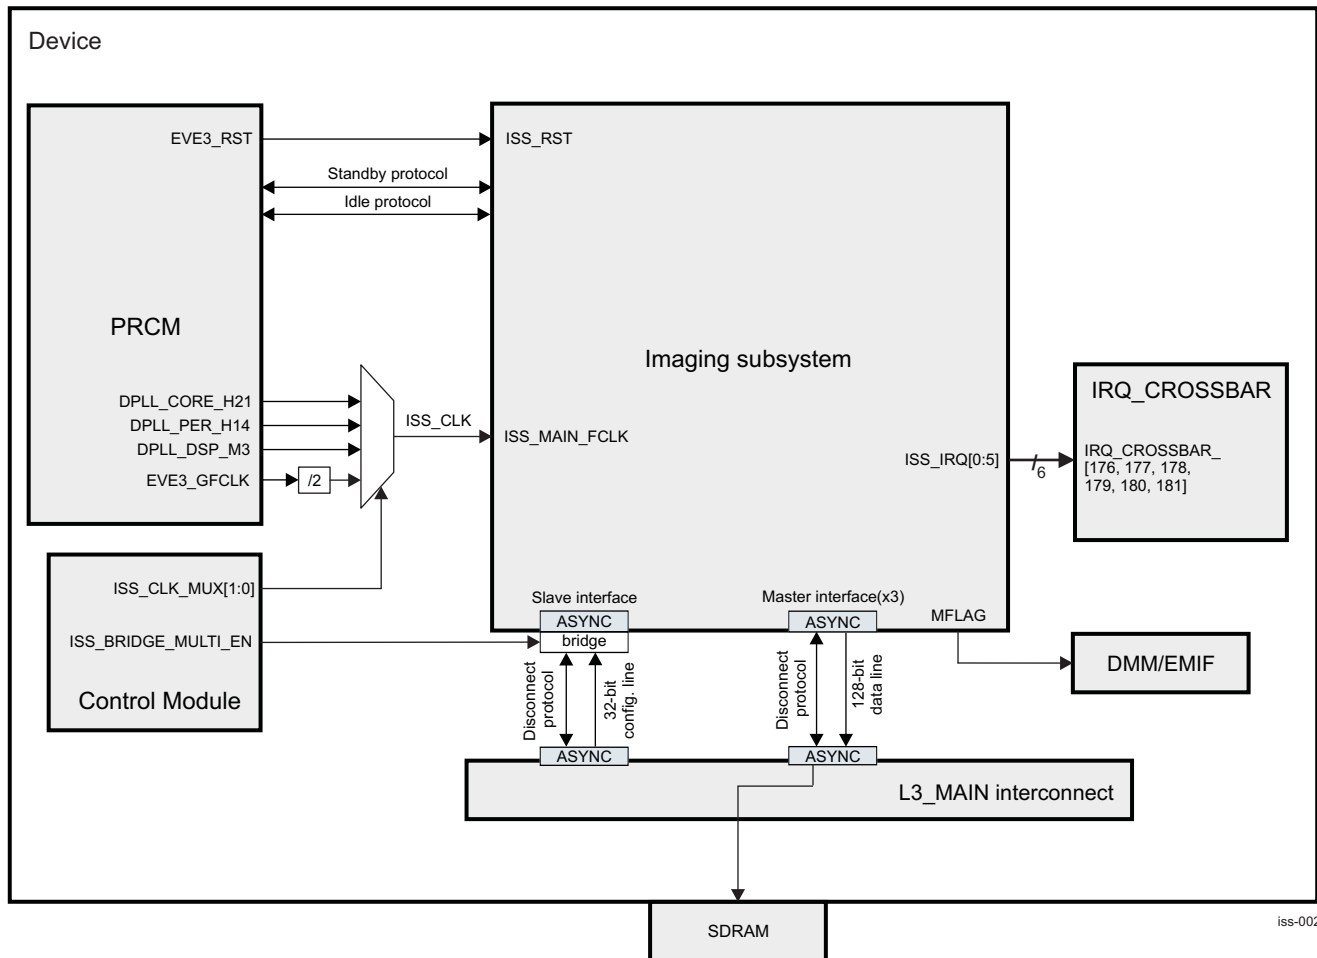

- ISP:
 - Memory-to-memory processing
 - Up to 532 MPix/s throughput
 - Statistic data collection
 - Image pipe interface front-end raw data processing
 - High-ISO video noise filtering (NSF3V)
 - Global and local contrast enhancement accelerator (GLBCE)
 - RGB and YUV data processing through ISIF and IPIPE
 - Two image continuous real-time resizers
 - Chroma noise filter
- CAL:
 - Memory-to-memory functional mode. Pixel data is read from memory, processed and then sent back to the system memory and/or ISP
- SIMCOP:
 - Memory-to-memory operation
 - Warping accelerator
 - Temporal video noise filter (VTNF)
 - Direct memory access (DMA) controller
 - Hardware sequencer
 - Mesh based lens distortion and perspective correction
- The ISS relies on the centralized memory management unit (MMU) within the SoC. See [Chapter 22, Memory Management Unit](#).

9.1.1 ISS Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 9-2 shows the ISS integration.

Figure 9-2. ISS Integration

iss-002

NOTE: For more information about the IDLE hardware handshake and wake-up request, see , *Module-Level Clock Management*, in [Chapter 3, Power, Reset, and Clock Management](#).

This section gives an overview of typical uses of the module. For more information about the relationship of the power, reset, and clock management (PRCM) module to the ISS clocks and the reset settings, see the detailed functional description in [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: For more information about the device clocks and how they are handled by the PRCM module before going into the ISS, see section *Clock Management Functional Description*, in [Chapter 3, Power, Reset, and Clock Management](#).

The ISS also supports software reset. A software reset has the same function as a hardware reset, except that it does not reset the power-management protocols.

[Table 9-1](#) through [Table 9-3](#) summarize the integration of the module in the device.

Table 9-1. ISS Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ISS	PD_EVE3	No	L3_MAIN

Table 9-2. ISS Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ISS	ISS_MAIN_FCLK	ISS_CLK (output of multiplexer)	PRCM	Functional clock for CAL_B, SIMCOP, ISP, and the interconnect (up to 532 MHz @ OPP_HIGH). For more information on supported OPPs and corresponding maximum clock frequencies, refer to device-specific Data Manual (DM). The source clock can be selected via CTRL_CORE_L3_INITIATOR_PRESSURE_7[1:0] ISS_CLK_MUX register bit-field in the device Control Module.

Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ISS	ISS_RST	EVE3_RST	PRCM	ISS global reset

Table 9-3. ISS Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
ISS	ISS_IRQ0	IRQ_CROSSBAR_176	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ1	IRQ_CROSSBAR_177	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ2	IRQ_CROSSBAR_178	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ3	IRQ_CROSSBAR_179	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ4	IRQ_CROSSBAR_180	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ5	IRQ_CROSSBAR_181	-	This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “Default Mapping” column in [Table 9-3 ISS Hardware Requests](#) shows the default mapping of module IRQ source signals. These module IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR. For more information about the IRQ_CROSSBAR module, see [Section 20.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 20, Control Module](#). For more information about the device interrupt controllers, see [Chapter 19, Interrupt Controllers](#).

9.1.1.1 ISS PRCM Interface Integration

9.1.1.1.1 ISS Clock Domains

The ISS has three asynchronous clock domains. Most of the logic uses ISS_MAIN_FLCK; the other clock domains are used for interfaces.

[Table 9-4](#) provides a high-level view of clocks. The frequencies provided are the values for OPP_HIGH. For more information on supported OPPs and corresponding maximum clock frequencies, refer to device-specific Data Manual.

Table 9-4. ISS Local Clock Domains

Name	Description
PCLK	CAL_B has video port output having its own pixel clock. This pixel clock is generated from the functional clock (ISS_MAIN_FCLK) and then provided to the ISP via multiplexing. Up to 532 MHz for OPP_HIGH.
ISS_MAIN_FLCK	Functional clock. It is used by all ISS submodules and ISS top-level resources. Up to 532 MHz for OPP_HIGH.

To save power, the ISS clocks can be divided at PRCM level. The PCLK must always be less or equal to the ISS_MAIN_FLCK. The internal configuration clock (CFGCLK, used for the internal ISS configuration network) is always half the ISS_MAIN_FLCK.

The functional clock of some submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the [ISS_CLKCTRL](#) register. Also, the pixel clocks sent by submodules to ISP can be cut off from the corresponding [ISS_CLKCTRL](#) bit-fields.

9.1.2 ISS Functional Description

This section provides only a top-level overview of the ISS. The ISS submodules are described in: [Section 9.2, ISS CAL](#), [Section 9.3, ISS ISP](#), and [Section 9.4, ISS SIMCOP](#).

9.1.2.1 ISS Interrupts

[Table 9-5](#) lists the events generated by the submodules and the top level of the ISS.

Each event that generates an interrupt can be individually enabled by setting the appropriate bit in the [ISS_HL_IRQENABLE_SET_i](#) register. The interrupt is disabled by setting the appropriate bit in the [ISS_HL_IRQENABLE_CLR_i](#) register.

When an event occurs, the corresponding bit in the [ISS_HL_IRQSTATUS_RAW_i](#) register is set regardless of whether or not the event is enabled. Bits in the [ISS_HL_IRQSTATUS_i](#) registers are set only when an enabled event occurs.

9.1.2.1.1 ISS Interrupt Merger

The ISS merges the interrupt sources listed in [Table 9-5](#) into six physical interrupt lines (ISS_IRQ0 to ISS_IRQ5). All six lines support level and pulse modes.

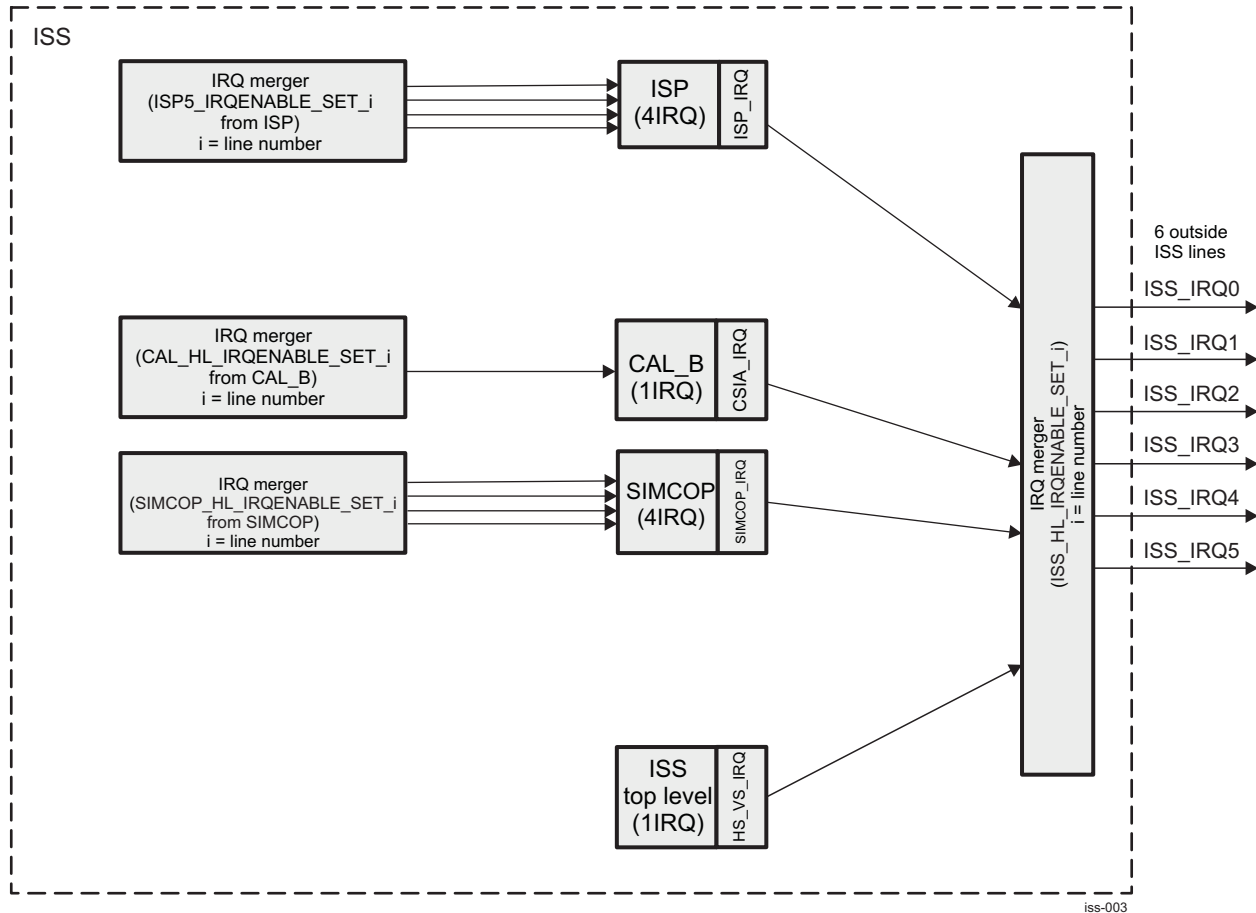

Table 9-5. ISS Interrupts⁽¹⁾

Interrupt	Source	Description
ISP_IRQ[3:0]	ISP	Interrupts generated by the ISP
CAL_B_IRQ	CAL_B	Interrupt generated by the CAL_B receiver
SIMCOP_IRQ[3:0]	SIMCOP	Interrupts generated by SIMCOP

⁽¹⁾ For more information, see also [Section 9.1.2.1.2, ISS Submodule Interrupts](#).

Software can select which interrupt sources are routed to each output line (ISS_IRQ[0:5]). All six physical interrupt outputs have equivalent functions. Software can use different interrupt lines to group events together by type and therefore reduce interrupt latencies. Typically, one interrupt line is used for low-priority events (errors), and the other interrupt lines are used for high-priority events (for example, SIMCOP sequencing and end-of-frame events to trigger configuration load). The ISS internal interrupt request (IRQ) merger (see [Figure 9-3](#)) relies only on level interrupts provided by submodules. Pulse interrupts provided by submodules are ignored. All of the interrupts are routed to device interrupt crossbar. Software does not need to clear events from submodules at the ISS level: it clears only the events at the submodule level. The IRQ merger automatically clears the IRQ at ISS level (events generated by submodules are automatically cleared at ISS level when they are cleared at sub-module level).

Figure 9-3. ISS Interrupt Merger

NOTE: For more information about the mapping of the six lines to the device modules outside ISS, see [Table 9-3](#).

The ISP, SIMCOP, CAL_B, and HL ISS merger IRQ lines are configurable. Each interrupt can be mapped to the required line.

9.1.2.1.2 ISS Submodule Interrupts

9.1.2.1.2.1 ISS ISP Interrupts

[Table 9-6](#) summarizes events that cause ISP interrupts.

Table 9-6. ISS ISP Interrupts

Event and Register ⁽¹⁾	Description
ISP5_IRQENABLE_SET_i[[31] OCP_ERR_IRQ	An interface port error has been received on the ISP master port.
ISP5_IRQENABLE_SET_i[[29] IPIPE_INT_DPC_RNEW1	HD interrupt signal to indicate the need to renew the defect pixel correction (DPC) table with new entries. The second 128 entries in the DPC table must be updated when this event triggers. This event is triggered when the 255th entry in the look-up table (LUT) is used. This interrupt is not synchronous to the HD signal.

⁽¹⁾ i = 0 to 3

Table 9-6. ISS ISP Interrupts (continued)

Event and Register ⁽¹⁾	Description
ISP5_IRQENABLE_SET_[28] IPIPE_INT_DPC_RNEW0	VD interrupt signal to indicate the need to renew the DPC table with new entries. The first 128 entries in the DPC table must be updated when the event triggers. This event is triggered when the 127th entry in the LUT is used. This interrupt is not synchronous to the HD signal.
ISP5_IRQENABLE_SET_[27] IPIPE_INT_DPC_INI	Interrupt to signal the need to initialize the DPC table. The DPC table contains two tables of 128 entries. When this signal is used, software must ensure that the 256 table entries are updated with the DPC information.
ISP5_IRQENABLE_SET_[25] IPIPE_INT_EOF	End of frame interrupt signal
ISP5_IRQENABLE_SET_[24] H3A_INT_EOF	End of frame interrupt signal
ISP5_IRQENABLE_SET_[22] RSZ_INT_EOF1	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[23] RSZ_INT_EOF0	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[19] RSZ_FIFO_IN_BLK_ERR	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[18] RSZ_FIFO_IN_OVF	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[17] RSZ_INT_CYC_RZB	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[16] RSZ_INT_CYC_RZA	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[15] RSZ_INT_DMA	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[14] RSZ_INT_LAST_PIX	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[13] RSZ_INT_REG	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[12] H3A_INT	Interrupt generated by the AF and AE/AWB blocks inside the H3A module. It indicates the end of processing a frame and is active high for one configuration bus clock cycle.
ISP5_IRQENABLE_SET_[11] AF_INT	AF inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish.
ISP5_IRQENABLE_SET_[10] AEW_INT	AEW inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish.
ISP5_IRQENABLE_SET_[9] IPIPEIF_IRQ	IPIPEIF module interrupt is generated at the start position of a frame and is active high for one configuration bus clock cycle.
ISP5_IRQENABLE_SET_[8] IPIPE_INT_HST	IPIPE module interrupt is generated when histogram is done.
ISP5_IRQENABLE_SET_[7] IPIPE_INT_BSC	IPIPE module interrupt is generated when boundary signal calculation is done.
ISP5_IRQENABLE_SET_[6] IPIPE_INT_DMA	IPIPE module interrupt is issued when the SDRAM transfer of boxcar is done. At this time, IPIPE EOF is sent to buffer logic.
ISP5_IRQENABLE_SET_[5] IPIPE_INT_LAST_PIX	IPIPE module interrupt is issued when the last pixel of a frame comes into IPIPE.
ISP5_IRQENABLE_SET_[4] IPIPE_INT_REG	IPIPE module interrupt is issued when the register update of the module is allowed.
ISP5_IRQENABLE_SET_[3] ISIF_INT_3	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[2] ISIF_INT_2	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[1] ISIF_INT_1	See Section 9.1.3, ISS Register Manual , and Section 9.3.4, ISS ISP Register Manual .

9.1.2.1.2.2 ISS CAL_B Interrupts

The CAL_B module also contains a high-level interrupt merger. For details on CAL_B interrupts and its IRQ merger refer to [Section 9.2.3.5, CAL Interrupt Events](#).

9.1.2.1.2.3 ISS SIMCOP Interrupts

[Table 9-7](#) summarizes the SIMCOP high-level interrupts mapped to the outer boundaries of the SIMCOP. For more information about interrupts generated from inside the SIMCOP modules, see [Section 9.4, ISS Still Image Coprocessor](#).

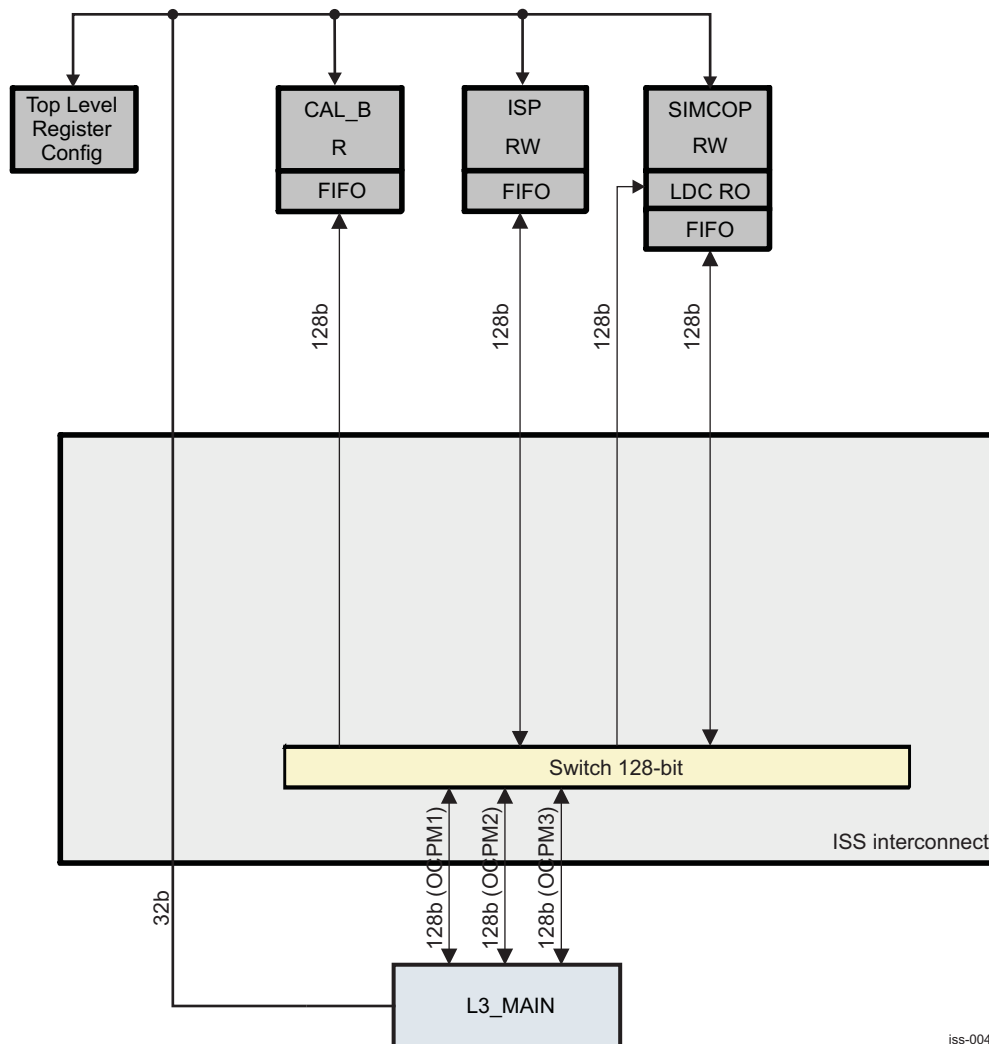

Table 9-7. ISS SIMCOP High-Level Interrupts

Event and Register	Description
SIMCOP_HL_IRQENABLE_SET_i[19] CPU_PROC_START_IRQ	Interrupt used when CPU data processing is used in a macroblock processing pipeline. When the CPU receives this IRQ, data is ready to be processed. When the CPU finishes processing the data, it acknowledges by setting the SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE bit.
SIMCOP_HL_IRQENABLE_SET_i[18] SIMCOP_DMA_IRQ1	Interrupt triggered by SIMCOP DMA
SIMCOP_HL_IRQENABLE_SET_i[16] OCP_ERR_IRQ	SIMCOP master port interface error
SIMCOP_HL_IRQENABLE_SET_i[14] DONE_IRQ	Event triggered when hardware sequencer finishes the sequence: <ul style="list-style-type: none"> The sequence step counter has reached the limit. All accelerator and DMA events for the last sequence step have been received.
SIMCOP_HL_IRQENABLE_SET_i[13] STEP3_IRQ	Event triggered when a SIMCOP Context 3 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[12] STEP2_IRQ	Event triggered when a SIMCOP Context 2 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[11] STEP1_IRQ	Event triggered when a SIMCOP Context 1 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[10] STEP0_IRQ	Event triggered when a SIMCOP Context 0 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[9] LDC_BLOCK_IRQ	A macroblock has been processed.
SIMCOP_HL_IRQENABLE_SET_i[1] LDC_FRAME_IRQ	A full frame has been processed.
SIMCOP_HL_IRQENABLE_SET_i[0] SIMCOP_DMA_IRQ0	Interrupt triggered by SIMCOP DMA

9.1.2.2 ISS Interconnect

Section 9.1.2.1.1 shows the ISS local interconnect data network.

Figure 9-4. ISS Local Interconnect Data Network

iss-004

The data network collects requests from CAL_B, ISP, and SIMCOP and forwards them to the L3_MAIN interconnect.

Table 9-8 summarizes what type of traffic can be generated by the different initiators on the ISS data interconnect and what targets can be addressed by those initiators.

Table 9-8. ISS Data Interconnect Connectivity Map

Initiator	Traffic type					Destination		
	RT / RD	RT / WR	NRT / RD	NRT / WR	2D	OCPM2	OCPM1 (RT)	OCPM3 (GP)
CAL_B		x	x	x		x	x	x
ISP	X	x	x	x		x	x	x
SIMCOP DMA			x	x	x	x		x
SIMCOP LDC			x			x		x

For destinations outside of the ISS, multiple routes are possible. Which one is chosen depends on the MReqInfo[1:0] field provided to the ISS data interconnect. Software can control the routing to some extent as shown in [Table 9-9](#)

Table 9-9. ISS Routing outside ISS boundaries

Initiator	MReqInfo (in)			Traffic type ⁽¹⁾	0 OCPM2	Routing - MReqInfo [1:0] (out)	
	Control	Value	Routing Control Register			1 OCPM2 (RT)	2 OCPM3 (GP)
CAL_B	Directly controlled by the CAL_B hardware.	0	ISS_ROUTE1.CALx_0	Cport #0 used for non real time traffic. Used by the read DMA. May require 1D->2D translation. Usage of RT port for non RT traffic not recommended	x	x	x
		>0	ISS_ROUTEx.CALx_1 ISS_ROUTEx.CALx_7	Typically used for real time traffic from the camera. Generally doesn't require translation. May be non real time in specific use cases. SL2 may be used to artificially increase the FIFO size	x	x	x
ISP	Directly controlled by the ISP HW.	0	ISS_ROUTE3.I SP_IPIPEIF	IPIPEIF RD : RT when used for DFS for data directly received from the camera; but generally used as read DMA in M2M mode	x	x	x
		1	ISS_ROUTE3.I SP_LSC	LSC RD : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		2	ISS_ROUTE3.I SP_RAW	ISIF RAW WR : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		3	ISS_ROUTE3.I SP_BOXCAR	IPIPE BOXCAR WR: RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		4	ISS_ROUTE3.I SP_H3A	H3A WR : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		5	ISS_ROUTE3.I SP_RSZA	RESIZER #A : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		6	ISS_ROUTE3.I SP_RSZB	RESIZER #B : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		7	NA	reserved	-	-	-
SIMCOP DMA	fixed		ISS_ROUTE3.SDMA	Non real time traffic. Chose route to minimize congestion	x		x
SIMCOP LDC	fixed		ISS_ROUTE3.LDC	Non real time traffic. Chose route to minimize congestion	x		x
Default							
Possible - depends on use case							
Not recommended							
Disallowed							

⁽¹⁾ Real-time (RT) traffic is not supported by ISS in this family of devices.

The above table shows MReqInfo[1:0] that are used to route the traffic. Moreover, ISS provides a different MReqInfo on the OCPM1 and OCPM2 to indicate the initiator ID to L3_MAIN. The [Table 9-10](#) lookup table inside the ISS is used to convert the 5-bit MReqInfo from the ISS into a 3-bit L3_MAIN MReqInfo. The lookup table is initialized with meaningful values but may be changed by software as shown below:

Table 9-10. ISS Initiator ID

ISS internal MReqInfo	Initiator	Register	Default L3_MAIN MReqInfo
0	ISP - IPIPEIF RD	ISS_REQINFO_MAP0_7.REQIN FO_0	0
1	ISP - ISIF LSC	ISS_REQINFO_MAP0_7.REQIN FO_1	0
2	ISP - ISIF RAW WR	ISS_REQINFO_MAP0_7.REQIN FO_2	0
3	ISP - IPIPE BOXCAR	ISS_REQINFO_MAP0_7.REQIN FO_3	0
4	ISP - H3A WR	ISS_REQINFO_MAP0_7.REQIN FO_4	0
5	ISP - RSZ #A	ISS_REQINFO_MAP0_7.REQIN FO_5	0
6	ISP - RSZ #B	ISS_REQINFO_MAP0_7.REQIN FO_6	0
7	ISP - reserved	ISS_REQINFO_MAP0_7.REQIN FO_7	0
8	reserved	ISS_REQINFO_MAP8_15.REQI NFO_8	0
9	reserved	ISS_REQINFO_MAP8_15.REQI NFO_9	0
10	SIMCOP DMA	ISS_REQINFO_MAP8_15.REQI NFO_10	1

Table 9-10. ISS Initiator ID (continued)

ISS internal MReqInfo	Initiator	Register	Default L3_MAIN MReqInfo
31	CAL_B WR CTX #7	ISS_REQINFO_MAP24_31.REQINFO_31	7

The default configuration has been optimized for typical memory to memory operation of ISP and SIMCOP. Some situations may require changing the configuration from the default; for example to balance the load between the interface master ports.

A fair arbitration is used among pending transactions with the same priority level (i.e. same MFlag value). Higher priority paths (i.e. larger MFlag value) always win the arbitration when they present a request. However, higher MFlags do not "reserve" a datapath when there is no pending transaction.

CAL_B and ISP can generate MFlag. ISP can assert its MFlag either statically (through SW configuration) or dynamically (FIFO level based; with SW configurable thresholds). Statically forcing MFlag to 01 or 11 is strongly discouraged as it reduces overall system efficiency. This possibility is offered by the HW only to workaround lately discovered HW bugs.

MFlag>0 generation shall be disabled for non real time traffic through adequate settings in the initiator IP.

CAL_B, ISP, and SIMCOP can generate up to 16 tags per master port. The number of tags that can be used per initiator is set by software (in the corresponding x_TAG_CNT register bit-fields). The ISS interconnect compresses the 6 x 16 internal ISS tags into 16 tags. Tag compression occurs after the 128-bit switch. When all 16 tags are used, the switch output is stalled. This stalls requests from ISS internal initiators.

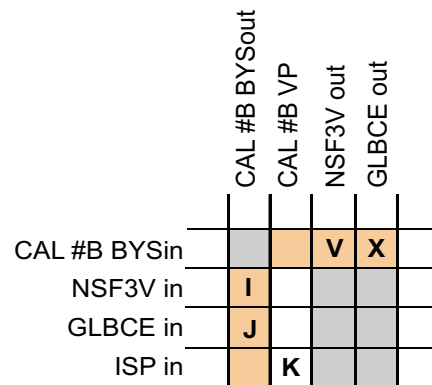

NOTE: There is another internal 32-bit configuration interconnect within the ISS. It runs on the internal CFGCLK, as explained in [Section 9.1.1.1.1, ISS Clock Domains](#). There is no physical link between the data and the configuration interconnect.

9.1.2.3 ISS Video Mux

The video mux connects video ports of different ISS sub-modules. [Figure 9-5](#) below summarizes all possible connections using the following conventions:

- Gray background indicates that this connection is meaningless:
 - Loop a module to itself
 - Create a connection that already exists (between NSF3V, GLBCE and ISP)
- White background indicates that a direct connection could potentially be implemented. But it is only implemented, if the box also contains a letter.
- Orange background indicates that a connection with width translation and/or frequency conversion is potentially possible (but not necessarily implemented).
- A letter indicates that a connection physically exists. It can be enabled by software (refer to [Table 9-12](#)).

Figure 9-5. ISS Video Mux Possible Connections

iss-007

Connections are enabled by selecting a source for each destination by configuring the relevant [ISS_VMUX](#) .[destination] register. Before changing a connection, SW shall ensure that pixel clocks of the old and the new sources are inactive. That can be guaranteed by disabling the clock with the relevant bit in [ISS_CLKCTRL](#). The video mux contains width and frequency conversion FIFO that should naturally drain their data. However, in some particular cases (e.g. path is stalled by the source and FIFO still contains data when the source is switched) it may be necessary to explicitly empty those using the [ISS_VMUX_RESET](#) register. In some cases, it may also be necessary to reset the data destination module to ensure that it starts from a clean state when the previous data stream was aborted. Once the video connection has been properly configured, SW should first enable the destination module and only enable the source module when the destination is ready to receive data.

It is possible that a given source is connected to multiple destinations (i.e. broadcast). Several paths support flow control (i.e. the source could be stalled when one of the destinations cannot accept the data to avoid data corruption). An error event is triggered when the source could not be stalled (because the data source doesn't support flow control).

The memory storage format used for the full resolution stream should match the format received from the camera. However, the format used by the CAL engine may be different.

Generally speaking, CAL_B is used as general purpose pixel read and write DMA engine.

ISP and either NSF3V or GLBCE can operate independently from each other and may be used in memory to memory mode when they are attached to pixel read and/or write DMA engine like CAL. The choice of the DMA depends on the use case requirements (i.e. available internal datapath, available processing resources, etc.)

[Table 9-11](#) summarizes the characteristics of the different source and destination video ports managed by the video mux.

Table 9-11. ISS Video Port Summary

Port	Type	Max. CLK (MHz) (OPP_HIGH) ⁽¹⁾	Channel #	Data width	HS	HE	VS	VE	FLD	WEN	STALL
CAL_B BYSin	Sink	532	4	16	X	X	X	X			
NSF3V in	Sink	532	1	16	X	X	X	X			X
GLBCE in	Sink	532	1	16	X	X	X	X			X
ISP in	Sink	532	1	16	X		X		X	X	X
CAL_B BYSout	Source	532	4	16	X	X	X	X			

⁽¹⁾ For more information on supported OPPs and corresponding maximum clock frequencies, refer to device-specific Data Manual.

Table 9-11. ISS Video Port Summary (continued)

Port	Type	Max. CLK (MHz) (OPP_HI GH) ⁽¹⁾	Channel #	Data width	HS	HE	VS	VE	FLD	WEN	STALL
CAL_B VP	Source	532	2	16	X	X	X	X			X

GLBCE out	Source	532	1	16	X	X	X	X			X

Table 9-12 summarizes how connections are physically implemented. It indicates for each possible connection shown in Figure 9-5

Table 9-12. ISS Video Mux Connection List

Path	SRC	Width translation	Freq converter	ISS_VMUX Register	ISS_VMUX_IRQ	Destination	Notes
I	CAL_B_BYS_OUT	W64_16_A	F304_426_D	NSF3V_IN=CAL_B_BYS_OUT	W64_16_A_OVR_IRQ F304_426_D_OVR_IRQ	NSF3V_IN	
J	CAL_B_BYS_OUT	W64_16_B	F304_426_D	GLBCE_IN=CAL_B_BYS_OUT	W64_16_B_OVR_IRQ F304_426_D_OVR_IRQ	GLBCE_IN	
K	CAL_B_OUT	W32_16_A	F304_426_E	ISP_IN=CAL_B_OUT	W32_16_A_OVR_IRQ F304_426_E_OVR_IRQ	ISP_IN	
V	NSF3V_OUT	W16_64_A	F426_304_B	CAL_B_BYS_IN=NSF3V_OUT	W16_64_A_OVR_IRQ F426_304_B_OVR_IRQ	CAL_B_BYS_IN	
X	GLBCE_OUT	W16_64_B	F426_304_B	CAL_B_BYS_IN=GLBCE_OUT	W16_64_B_OVR_IRQ F426_304_B_OVR_IRQ	CAL_B_BYS_IN	

The data source may generate additional horizontal blanking (PCLK pulses between HE and HS) and vertical blanking (additional lines) that is always forwarded to the destination accordingly to the performed width translation (that is, one PCLK pulse translates into 4 PCLK pulses in a 4->1 width translation bridge) and frequency translation (that is, one PCLK pulse in the source clock domain translates into one PCLK pulse in the destination clock domain). Therefore, a pixel clock that is too fast could also lead to a FIFO overflow in a down conversion. It is SW responsibility to set a suitable pixel clock using PCLK divider in the data source, if available.

9.1.2.4 ISS Clocks

The clocks of ISS submodules can be cut individually using the [ISS_CLKCTRL](#) register. Software can poll the module status reading the appropriate bit in the [ISS_CLKSTAT](#) register.

When software wants to enable a submodule:

- Software sets the appropriate bit in the [ISS_CLKCTRL](#) register.
- Hardware enables the submodule functional and interface clocks (expected to take a few cycles).
- Hardware sets the appropriate bit in the [ISS_CLKSTAT](#) register.

Software must enable the modules in the correct order. The hardware imposes no particular constraint. For example, when data must be provided by CAL_B and processed by the ISP, both modules must be enabled and correctly configured before data arrives. For details and the order of configuration, see the programming model of the particular submodule.

When software wants to shut down a submodule:

- Software ensures that the submodule is idle. Mainly:
 - The submodule must not generate new events.
 - The submodule must not have any pending events.
 - For initiators: The submodule must stop the generation of an interface bridge transaction.
- Software clears the appropriate bit in the [ISS_CLKCTRL](#) register.
- For modules having only a master port: Hardware waits until the submodule to be disconnected asserts the MStandBy signal on its master port. It asserts MWait of the submodule.

NOTE: The ISS does not assert the MWait signal when a shutdown of the module is not requested by software.

- Hardware cuts the submodule clocks.
- Hardware clears the appropriate bit in the [ISS_CLKSTAT](#) register.

[Table 9-13](#) describes the clock gating of the ISS submodule.

Table 9-13. ISS Submodule Clock Gating

ISS Resource	Feature On/Off Control
ISS top-level resources	Not applicable. ISS top-level resources cannot be cut. However, top-level resources support the autogating feature.
SIMCOP	ISS_CLKCTRL[0] SIMCOP
ISP	ISS_CLKCTRL[1] ISP
CAL_B	ISS_CLKCTRL[10] CAL_B
ISS interconnect	These modules cannot be switched off individually. They are required for any processing performed by SIMCOP because they are on the main data path. However, they support autogating to reduce power consumption when activity is low.

When the clock of a submodule is cut and an interface bridge request for this module is received from the ISS configuration interconnect, the ISS clock manager temporarily enables the module clock to handle the access properly.

All ISS submodules are off after reset; software must enable them before they can be used.

9.1.2.5 ISS Reset

The ISS can accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset.

1. Set the [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET bit to 1.
2. Read the [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET bit to check whether it equals 0, which means the reset occurred.

If after five reads, [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET still returns 1, it can be assumed that an error occurred during the reset stage.

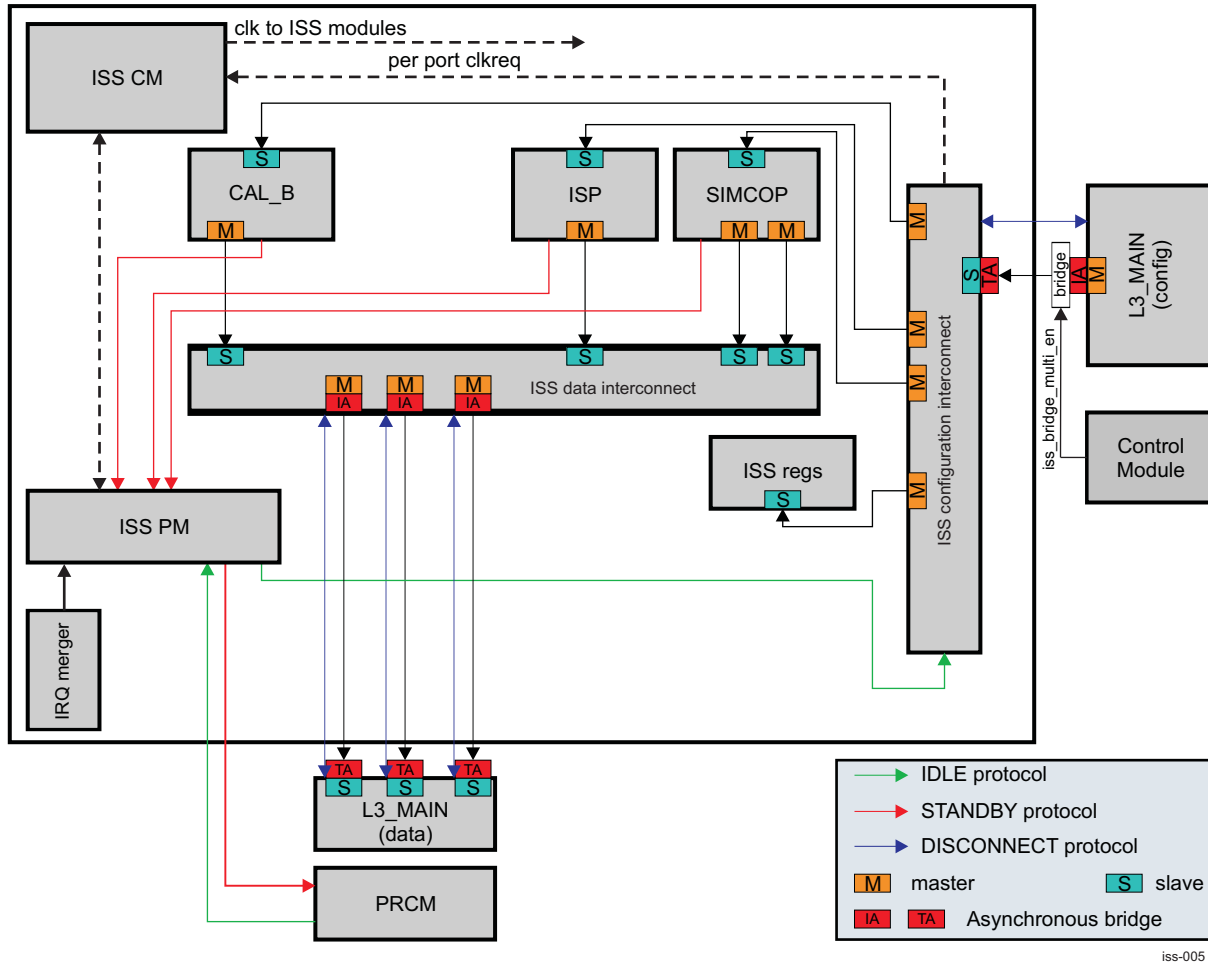

A software reset must not reset the power manager protocols (must not reset the IDLE and STANDBY generic IPs).

9.1.2.6 ISS Power Management

9.1.2.6.1 ISS Power-Management Infrastructure Overview

Figure 9-6 is an overview of the ISS power management.

Figure 9-6. ISS Power Management

iss-005

NOTE: For power savings, the PRCM module can request idle mode from the ISS. When the ISS is not functional, software must decide when the PRCM module can send the request. For more information, see , *Module-Level Clock Management*, in [Chapter 3, Power, Reset, and Clock Management](#).

9.1.2.6.2 ISS STANDBY Mechanism

The power manager receives STANDBY information from the CAL_B, ISP, and SIMCOP modules. These modules assert a standby signal when they have no more transactions to perform. The ISS power manager acknowledges by asserting a wait signal.

When those modules are in standby mode, the ISS power manager initiates a STANDBY sequence for the ISS:

1. The ISS waits while the CAL_B, ISP, and SIMCOP MStandby is asserted.
2. The ISS power manager acknowledges by asserting the CAL_B, ISP, and SIMCOP MWait signal.
3. The ISS initiators assert only the MStandBy signal when they receive responses to all sent requests. Therefore, when all initiators have asserted MStandBy, the ISS interconnect has no more pending

traffic (although configurable, only nonposted writes must be used for error reporting).

4. The ISS power manager asserts the MStandBy signals connected to the system PRCM module.
5. The PRCM module acknowledges by asserting the MWait signal.

A functional standby transition can be aborted when one of the CAL_B, ISP, and SIMCOP modules deasserts the MStandBy signal.

When one of the CAL_B, ISP, and SIMCOP modules must perform accesses to the ISS interface master port, it deasserts the MStandBy signal. The ISS power manager executes the following sequence to leave the STANDBY state:

1. The ISS power manager deasserts the MStandby signal.
2. The ISS waits until the PRCM module deasserts the MWait signal.
3. The ISS deasserts the MWait signal of the module requesting access.

Abort of the standby-to-functional mode transition is not supported. The ISS power manager completes the standby-to-functional transition and then allows a new functional-to-standby transition.

Typically, the MStandby signal is used for two purposes. Software chooses one of the following behaviors through PRCM configuration:

- During blanking periods: The ISS asserts the MStandBy signal between frames when it has no more data to send. The PRCM module can use this information to switch off the L3_MAIN interconnect and save some dynamic power. However, the PRCM module is not allowed to cut the ISS functional clock in that case, because it is needed to receive the next frame.
- For ISS shutdown: The ISS asserts MStandBy when it has no more transactions to perform. The PRCM module then initiates an IDLE sequence. Once the ISS acknowledges the transition into idle mode, the PRCM module can cut the ISS clock and power.

The internal standby mode can be reached only when CAL_B, SIMCOP, ISP, and ISS data interconnect are in IDLE or STANDBY state. Choosing no-idle or no-standby mode for any of these modules prevents the ISS from going into STANDBY state.

Four modes for standby control are supported, configured through the [ISS_HL_SYSCONFIG](#) [5:4] STANDBYMODE register bit-field:

- Smart-standby-wakeup mode [STANDBYMODE = 0x3]: This is the mode normally used. When in this mode, the ISS asserts the MStandBy signal when the MStandBy of all ISS internal initiators is asserted and the ISS data interconnect are in IDLE state.
- Smart-standby mode (default) [STANDBYMODE = 0x2]: The ISS has no wake-up event. This mode is equivalent to smart-standby-wakeup mode.
- Force-standby mode [STANDBYMODE = 0x0]: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS asserts MStandBy unconditionally. Software must ensure that the ISS is in a correct quiet state before programming this mode.
- No-standby mode [STANDBYMODE = 0x1]: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS never asserts the MStandBy signal.

9.1.2.6.3 ISS IDLE Mechanism

The PRCM module can request the ISS to go into IDLE state when the ISS has asserted its MStandBy output.

In a normal case, software must ensure that the ISS is in a quiet state before allowing the PRCM module to send an IDLE request to the ISS:

- The ISS has no more traffic to generate.
- The ISS cannot generate any new interrupts.
- The ISS has no pending interrupts.

When an IDLE request is received from the PRCM module, the ISS power manager verifies that the ISS MWait input has been asserted and that all ISS interrupt outputs are deasserted. It then starts the STANDBY-to-IDLE transition:

1. Send IDLE request to the ISS configuration interconnect.

2. The ISS configuration interconnect requests disconnection of both ISS interface slave ports. Disconnection is done by the master:
 - It stops accepting new requests and drains currently ongoing ones.
 - It waits for completion of all ongoing transactions.
3. The ISS configuration interconnect acknowledges the IDLE transition.
4. The ISS power manager acknowledges the IDLE request from the PRCM module.
5. The PRCM module can cut the ISS clock and power.

The PRCM module first enables the ISS power and clock before requesting the ISS to go into functional state by deasserting the `IdleReq` signal. The ISS power manager then executes the wake-up sequence:

1. Request the ISS interconnect to go into functional state.
2. The ISS interconnect connects the ISS slave ports.
3. The ISS interconnect acknowledges transition into functional mode.
4. The ISS power manager acknowledges transition into functional mode (ISS output `IdleAck` = 00).

Four modes for IDLE control are supported, controlled through the `ISS_HL_SYSCONFIG[3:2]` IDLEMODE register bit-field:

- Smart-idle-wakeup mode [IDLEMODE = 0x3]: This is the mode normally used. When in this mode, the ISS acknowledges a request to go idle from the power manager after having performed all hardware operations necessary for the IAF to be in a correct quiet state.
- Smart-idle mode (default) [IDLEMODE = 0x2]: This is equivalent to smart-idle-wakeup mode.
- Force-idle mode [IDLEMODE = 0x0]: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, the ISS acknowledges a request to go idle from the power manager with no hardware condition. Software must ensure that the ISS is in a correct quiet state before requesting a force-idle transition.
- No-idle mode [IDLEMODE = 0x1]: When in this mode, the ISS disregards any request to go idle from the power manager.

9.1.2.7 ISS CAL Usage Considerations

ISS provides a single CAL module (`CAL_B`) which can be used as read DMA engine and either stream the data to ISP or write it back to memory.

9.1.2.7.1 CAL Usage as Memory to Memory Pixel DMA

CAL can be used to operate the complete ISP, NSF3V (ISP sub-module) or GLBCE (ISP sub-module) in memory-to-memory mode. From ISP point of view CAL is only used as a data read DMA while the ISP internal write masters transfer pixel data back to memory. NSF3V and GLBCE do not have their own DMA engines and therefore rely on CAL to read and write the pixel stream from/to memory.

The recommended data flows for CAL usage are:

1. DDR memory -> `CAL_B` Read DMA -> `CAL_B` Video Port -> ISS Video Mux K -> ISP -> DDR memory
2. DDR memory -> `CAL_B` Read DMA -> `CAL_B` BYS Output Port -> ISS Video Mux J -> GLBCE Input -> GLBCE Output -> ISS Video Mux X -> `CAL_B` BYS Input Port -> `CAL_B` Write DMA -> DDR memory
3. DDR memory -> `CAL_B` Read DMA -> `CAL_B` BYS Output Port -> ISS Video Mux I -> NSF3V Input -> NSF3V Output -> ISS Video Mux V -> `CAL_B` BYS Input Port -> `CAL_B` Write DMA -> DDR memory
4. DDR memory -> `CAL_B` Read DMA -> `CAL_B` BYS Output Port -> ISS Video Mux J -> GLBCE Input -> GLBCE Output -> ISS Video Mux X -> `CAL_B` BYS Input -> `CAL_B` Video Port -> ISS Video Mux K -> ISP -> DDR memory

At CAL module level, the data rates for memory-to-memory traffic are controlled by the `CAL_RD_DMA_CTRL[31:15]` PCLK register bit-field. See [Section 9.2, ISS Camera Adapter Layer \(CAL\)](#), for CAL register information.

CAL shall not send data to the attached modules (NSF3V, ISP, GLBCE) at a higher rate than what it could process without creating back pressure (assert STALL signal). CAL does not have STALL support on its BYS input port, therefore attempts to create back pressure would lead to data corruption.

Software shall not allow memory-to-memory traffic to fill up the FIFO of CAL Write DMA. Otherwise, the FIFO would overflow in case of backpressure from the system. Generally, the memory-to-memory stream should be stalled when there is only 1~2kB of space left in the FIFO:

- Set CAL_CTRL[22] RD_DMA_STALL = 1 and configure CAL_CTRL[23:13] MFLAGL register field to trigger 2kB before the FIFO is full (value could be adapted for specific use case needs). Therefore, CAL Read DMA will stop sending additional data into the CAL shared pipeline when less than 2kBytes of space is left in the Write DMA FIFO.
- CAL_CTRL[31:24] MFLAGH register field shall be set to trigger 1kB bytes before the FIFO is full (value could be adapted for specific use case needs). Therefore, no additional data will be accepted from NSF3V/GLBCE when less than 1kBytes of space is left in the Write DMA FIFO.

CAL BYS ports do not support back pressuring of the dataflow. Therefore, when data arrives faster than expected on the CAL BYS input port, an overflow condition will occur in the CAL. Similarly, when CAL BYS output port sends data to NSF3V or GLBCE at faster than expected rate, an overflow condition will occur.

9.1.2.7.2 CAL Usage with GLBCE

The ISS GLBCE module requires ~5400 clock pulses after startup before it could receive data from its video port. Therefore, before the the CAL -> GLBCE -> CAL data path could be used after a GLBCE reset, SW shall use the following sequence to provide those required clock pulses:

1. Configure the ISS Video Mux to not send the CAL BYS output data stream to GLBCE and to not send the GLBCE output data stream to CAL BYS input port. See [Section 9.1.2.3, ISS Video Mux](#), for more details.
2. Set CAL_BYS_CTRL2[11] FREERUNNING register bit. Refer to [Section 9.2, ISS Camera Adapter Layer \(CAL\)](#), for CAL register information.
3. Configure CAL Read DMA to read a dummy frame of 8 pixels x 1 line and write it out to BYS output port. This dummy frame is needed to start generation of the free running PCLK as BYS registers are shadowed. Therefore, changes are only taken into account at frame start (that is, the start of the dummy frame in this case).
4. Wait for the IRQ_BYSOUT_EOF interrupt event at CAL module level. CAL continues to generate a free-running PCLK at this point.
5. Configure the ISS Video Mux to enable the following data path: CAL BYS output port -> GLBCE input -> GLBCE output -> CAL BYS input port. Therefore, GLBCE receives the free-running PCLK, but not the HS/HE/VS/VE of the dummy frame.
6. Wait for the GLBCE_FILTERING_DONE event. It indicates that GLBCE has received enough PCLK pulses for internal initialization and that it is now ready to receive pixels.
7. Configure GLBCE and CAL for the actual frame processing.

9.1.3 ISS Register Manual

9.1.3.1 ISS Instance Summary

Table 9-14 is the ISS instance.

Table 9-14. ISS Instance Summary

Module Name	Module Base Address	Size
ISS_TOP	0x4220 0000	364 bytes

NOTE: This section contains the ISS TOP registers only. For submodule register details, see the register manual of the particular submodule.

LVDSRX, CAL_A, PPI, CSI-2, CSI-3, ICM, CCP2, BYS, and CTSET modules and associated features are not supported in this family of devices.

9.1.3.2 ISS Registers

9.1.3.2.1 ISS TOP Register Summary

Table 9-15 summarizes the ISS TOP register mapping.

26	LVDSRX0_IRQ	Event generated by LVDSRX 0x0: No action 0x1: Disable interrupt	RW	0x0
25	ICM_A_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
24	ICM_B_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
23	CAL_B_IRQ	Event generated by CAL #B 0x0: No action 0x1: Disable interrupt	R	0x0
22	CAL_A_IRQ	Event generated by CAL #A 0x0: No action 0x1: Disable interrupt	RW	0x0
21	RESERVED	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
20	BYS_B_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
19	VMUX_IRQ	Event generated by VMUX 0x0: No action 0x1: Disable interrupt	RW	0x0
18	BYS_A_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
17	HS_VS_IRQ	HS or VS synchronization event. This event is triggered if a rising or falling edge is detected on the HS or VS signal (after the video port mux). The rising or falling edge and the HS or VS signal selection is chosen with the ISS_CTRL.SYNC_DETECT bit field. 0x0: No action 0x1: Disable interrupt	RW	0x0
16	CCP2_IRQ8	This bit field is reserved and users should write the reset value to this bit location.	R	0x0

Bits	Field Name	Description	Type	Reset
15	SIMCOP_IRQ3	Event generated by SIMCOP 0x0: No action 0x1: Disable interrupt	RW	0x0
14	SIMCOP_IRQ2	Event generated by SIMCOP 0x0: No action 0x1: Disable interrupt	RW	0x0
13	SIMCOP_IRQ1	Event generated by SIMCOP 0x0: No action 0x1: Disable interrupt	RW	0x0
12	SIMCOP_IRQ0	Event generated by SIMCOP 0x0: No action 0x1: Disable interrupt	RW	0x0
11	BTE_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
10	CBUFF_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
9	CCP2_IRQ3	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
8	CCP2_IRQ2	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
7	CCP2_IRQ1	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
6	CCP2_IRQ0	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
5:4	RESERVED	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
3	ISP_IRQ3	Combined interrupt event provided by the ISP. 0x0: No action 0x1: Disable interrupt	RW	0x0
2	ISP_IRQ2	Combined interrupt event provided by the ISP. 0x0: No action 0x1: Disable interrupt	RW	0x0
1	ISP_IRQ1	Combined interrupt event provided by the ISP. 0x0: No action 0x1: Disable interrupt	RW	0x0
0	ISP_IRQ0	Combined interrupt event provided by the ISP. 0x0: No action 0x1: Disable interrupt	RW	0x0

- [ISS TOP Register Summary: \[8\]](#)

9.2 ISS Camera Adapter Layer (CAL)

The Camera Adapter Layer (CAL_B) module within the ISS boundary is targeted as a read DMA engine which together with the Image Signal Processor (ISP) is used for memory to memory data transfer operations.

9.2.1 ISS CAL Features

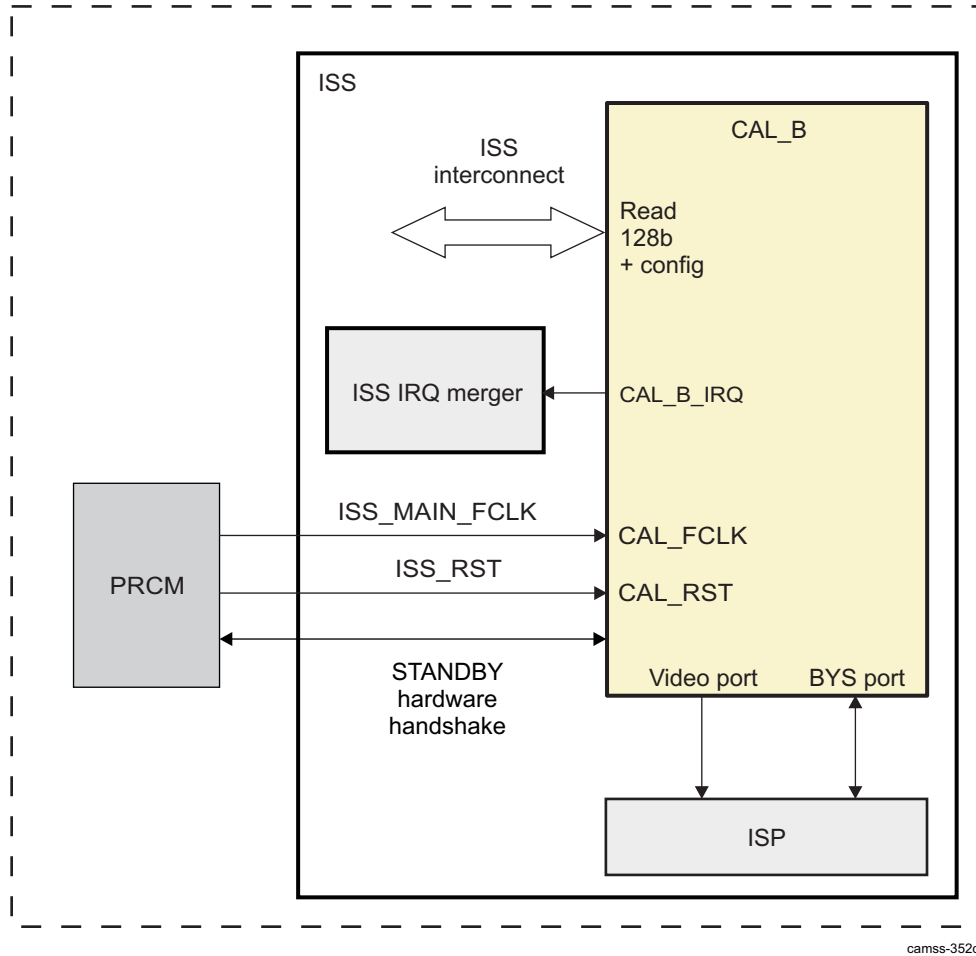

The ISS CAL module provides the following main features:

- Up to 532 MPix/s throughput
- Interfaces:
 - 32-bit slave configuration interface (OCPC)
 - 128-bit master data interface (OCPO) for memory to memory data transfer operations
 - Video output port for interconnection with the ISP IPIPEIF module.
 - Up to 2 pixels per clock cycle
 - Pixel rate smoothing buffer of 1k pixels
 - Flow control
 - BYS output and input ports for interconnection with the ISP GLBCE and NSF3V modules (up to 4 pixels per clock cycle)
- Memory-to-memory functional mode: Pixel data is read from memory, processed and then sent back to the system memory, video port and/or BYS port
- Up to four [4] independent pixel processing contexts:
 - Extract pixels from byte stream
 - DPCM decompression (4 pixels/cycle for predictor1; 1 pixel/cycle for predictor2)
 - DPCM compression (2 pixels/cycle for predictor1; predictor2 is not supported)
 - Pixel packing into a byte stream (for memory storage)
- Up to eight [8] independent write DMA contexts:
 - Write header, pixel or attribute data
 - Horizontal cropping
 - Pack data from independent streams into efficient OCP transactions
 - 1D and 2D addressing modes (only INCR bursts)
 - Resynchronize on line boundaries (for TxBuffer overflows)
 - Linear, circular and sub-sampled addressing modes
- One read DMA engine:
 - Read DPCM decoder initialization and pixel data
 - Send data through the complete processing pipeline
 - YUV420 to YUV422 up-sampling
 - Linear, circular and sub-sampled addressing modes

9.2.2 ISS CAL Integration

This section describes the integration of CAL_B module in the device and within ISS boundary, including information about clocks, resets, and hardware requests.

Figure 9-7. CAL Integration

camss-352c

NOTE: For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

9.2.2.1 CAL Main Integration Attributes

This section describes the CAL integration in the device, including information about clocks, resets, and hardware requests.

[Table 9-78](#) through [Table 9-80](#) summarize the integration of the module in the device.

Table 9-78. CAL Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
CAL_B	PD_EVE3	No	L3_MAIN through the internal ISS interconnect for configuration and data transfers from/to system memory.

Table 9-79. CAL Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CAL_B	CAL_FCLK	ISS_MAIN_FCLK	ISS	Functional clock
	CAL_ICLK	ISS_MAIN_FCLK / 2	ISS	Configuration clock equal to 1/2 of the CAL_FCLK.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CAL_B	CAL_RST	ISS_RST	ISS	CAL_B global hardware reset

Table 9-80. CAL Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination ISS_CROSSBAR Input	Default Mapping	Description
CAL_B	CAL_B_IRQ	N/A (connected to ISS IRQ merger)	-	CAL_B interrupt request

9.2.2.2 CAL Integration - Video Port

CAL_B module has a single output video port for data transfer to the ISP module.

[Table 9-81](#) summarizes the video port interface signals

Table 9-81. CAL Video Port Signals

Signal name	I/O	Description
VP_PCLK	O	Output pixel clock. Synchronous to the functional clock. Mean clock rate defined by the CAL_VPORT_CTRL1[16:0] PCLK register bit-field.
VP_VS	O	Active during the first pixel of the frame
VP_VE	O	Active during the last pixel of the frame
VP_HS	O	Active during the first pixel of any line
VP_HE	O	Active during the last pixel of any line
VP_DATA[15:0]	O	When CAL_VPORT_CTRL1[31] WIDTH = 0: Pixel data for any position When CAL_VPORT_CTRL1[31] WIDTH = 1: Pixel data for position (X%2) = 0 MSBs padded with 0s when less than 16 bits are used.
VP_DATA[31:16]	O	When CAL_VPORT_CTRL1[31] WIDTH = 0: Stuffed with 0s for any position When CAL_VPORT_CTRL1[31] WIDTH = 1: Pixel data for position (X%2) = 1 MSBs padded with 0s when less than 16 bits are used.
VP_STALL	I	Hardwired to 0. Video port cannot be stalled from outside of CAL.

Software can control the minimum time between two consecutive VP_PCLK pulses using the [CAL_VPORT_CTRL1\[16:0\]](#) PCLK bit field. It can also impose minimum vertical and horizontal blanking using the [CAL_VPORT_CTRL1\[24:17\]](#) XBLK and [CAL_VPORT_CTRL1\[30:25\]](#) YBLK bit fields.

The video port can carry up to 2 pixels per cycle.

Video port timings and waveforms are nearly the same as for the output BYS port (see [Figure 9-8](#)). The only differences are that the video port can only carry up to 2 pixels per cycle, and has dedicated control registers/data source.

More details about the video port are provided in [Section 9.2.3.12, CAL Video Port](#).

9.2.2.3 CAL Integration - BYS Ports

The CAL module has one BYS port for data input (BYS_PI) and another BYS port for data output (BYS_PO).

The BYS ports are 4 × 16 bits wide and carry 4 or 0 pixels per cycle. Pixels are LSB aligned inside 16-bit containers on the bus.

[Table 9-82](#) and [Table 9-83](#) summarize the BYS ports interface signals.

Table 9-82. CAL BYS Input Port Signals

Signal name	I/O	Description
BYS_PI_PCLK	I	Pixel clock received from the ISS ISP. Asynchronous from the functional clock. The mean pixel clock must be less or equal to the functional clock (CAL_FCLK). The base clock used to generate this pixel clock may be up to 304 MHz.
BYS_PI_VS	I	Active during the 1st pixel of the frame
BYS_PI_VE	I	Active during the last pixel of the frame
BYS_PI_HS	I	Active during the 1st pixel of any line
BYS_PI_HE	I	Active during the last pixel of any line
BYS_PI_DATA[15:0]	I	Pixel data for position (X%4)=0. MSBs padded with 0s when less than 16 bits are used.
BYS_PI_DATA[31:16]	I	Pixel data for position (X%4)=1. MSBs padded with 0s when less than 16 bits are used.
BYS_PI_DATA[47:32]	I	Pixel data for position (X%4)=2. MSBs padded with 0s when less than 16 bits are used.
BYS_PI_DATA[63:48]	I	Pixel data for position (X%4)=3. MSBs padded with 0s when less than 16 bits are used.

Table 9-83. CAL BYS Output Port Signals

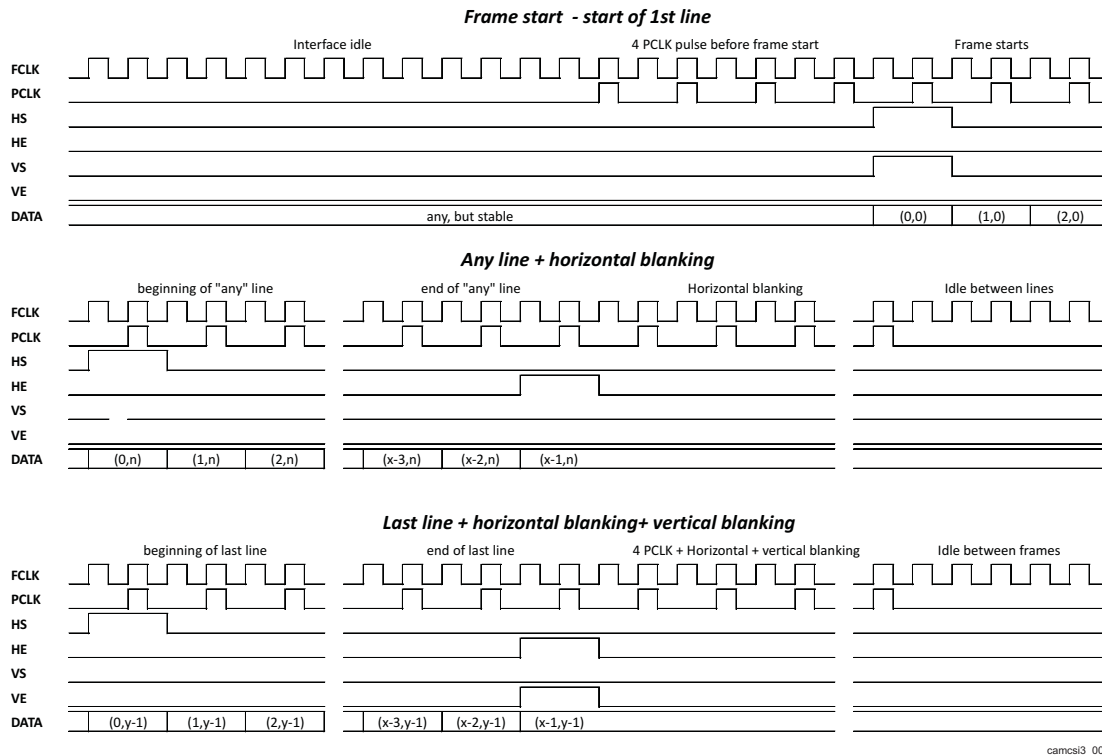

Signal name	I/O	Description
BYS_PO_PCLK	O	Pixel clock provided to the ISS ISP. Synchronous to the functional clock. Mean clock rate defined by the CAL_BYS_CTRL1[16:10] PCLK bit field.
BYS_PO_VS	O	Active during the 1st pixel of the frame
BYS_PO_HS	O	Active during the 1st pixel of any line
BYS_PO_DATA[15:0]	O	Pixel data for position (X%4)=0. MSBs padded with 0s when less than 16 bits are used.
BYS_PO_DATA[31:16]	O	Pixel data for position (X%4)=1. MSBs padded with 0s when less than 16 bits are used.
BYS_PO_DATA[47:32]	O	Pixel data for position (X%4)=2. MSBs padded with 0s when less than 16 bits are used.
BYS_PO_DATA[63:48]	O	Pixel data for position (X%4)=3. MSBs padded with 0s when less than 16 bits are used.

The BYS input video port is asynchronous to the functional clock (CAL_FCLK). The DATA, HS, VS, HE and VE signals are sampled on the rising edge of BYS_PI_PCLK.

The BYS output video port is synchronous to CAL_FCLK clock. The data rate is imposed by the data arrival rate from memory. Software can impose a minimum time between two consecutive clock pulses using the [CAL_BYS_CTRL1\[16:10\]](#) PCLK bit field. It can also impose blanking times with active pixel clock using the [CAL_BYS_CTRL1\[24:17\]](#) XBLK and [CAL_BYS_CTRL1\[30:25\]](#) YBLK bit fields. The DATA, HS and VS signals are generated on the functional clock (CAL_FCLK) cycle before the next BYS_PO_PCLK edge. The BYS port is therefore timed for full functional clock speed.

[Figure 9-8](#) and [Table 9-84](#) provide examples for BYS input port timings and pixel data transaction.

Figure 9-8. CAL BYS Input Port Timing Example

camcsi3_003

Table 9-84. CAL BYS Input Port Transaction Example

Cycle Number	HS	HE	VS	VE	DATA [11:0]	DATA [15:12]	DATA [27:16]	DATA [31:28]	DATA [43:32]	DATA [47:44]	DATA [59:48]	DATA [63:60]
1	0	0	0	0	Any Data							
2	0	0	0	0	Any Data							
3	0	0	0	0	Any Data							
4	0	0	0	0	Any Data							
5	1	0	1	0	Pixel 0	0s	Pixel 1	0s	Pixel 2	0s	Pixel 3	0s
6	0	0	0	0	Pixel 4	0s	Pixel 5	0s	Pixel 6	0s	Pixel 7	0s
N ⁽¹⁾	0	1	0	0	Last pixel	0s	0s	0s	0s	0s	0s	0s

⁽¹⁾ Example where the width is not a multiple of 4

The BYS_PI_PCLK/BYS_PO_PCLK pulses are not necessarily regularly spaced.

There must be at least four BYS_PI_PCLK/BYS_PO_PCLK pulses before the first pixel of a frame (that is, after reset) and there must be at least four BYS_PI_PCLK/BYS_PO_PCLK cycles of vertical blanking after the frame end. Therefore, there must be at least eight PCLK cycles between two consecutive frames.

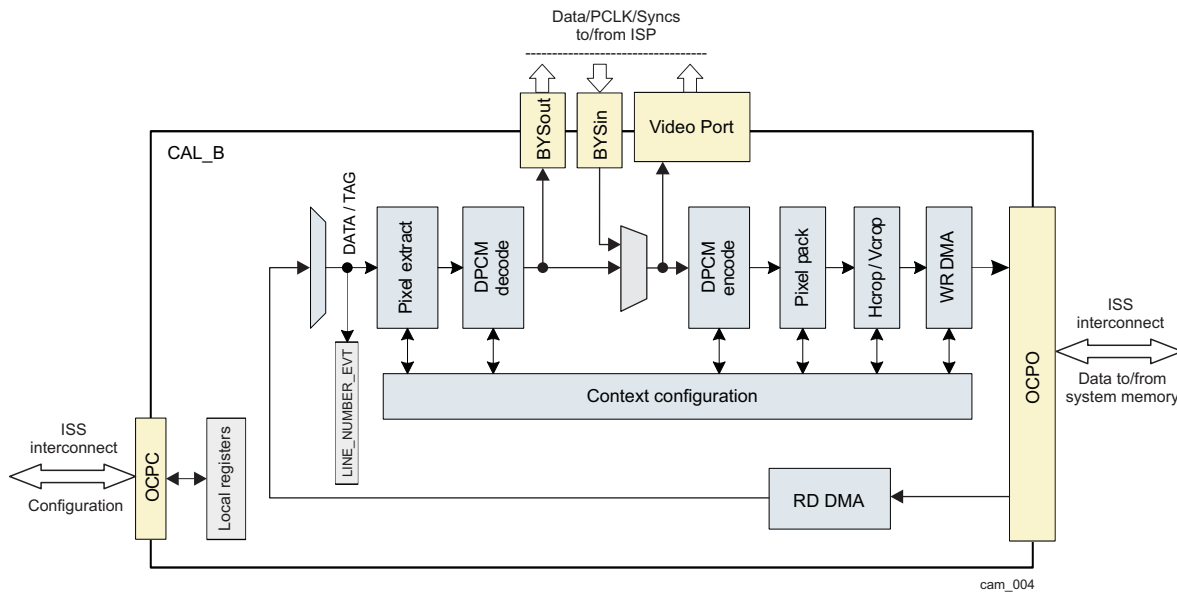

More details about the BYS ports are provided in [Section 9.2.3.13, CAL BYS Ports](#).

9.2.3 ISS CAL Functional Description

9.2.3.1 CAL Block Diagram

Figure 9-9 shows an overview block diagram of the CAL_B module.

Figure 9-9. CAL_B Block Diagram

The RD DMA block reads pixel data from memory and re-formats the data into a stream understood by the CAL processing pipeline.

The data is sent with 64-bit granularity to the CAL pipeline for further processing. The data pipeline forwards 64-bit wide data words as well as a 5-bit wide data qualifier + 4-bit validity qualifier + 5-bit CPORT number (referred as TAG in this chapter).

The TAG is set by the data source and controls how the different stages in the processing pipeline behave. Figure 9-10 summarizes possible values for the data qualifier and the corresponding behavior of the different processing stages:

Figure 9-10. CAL Data Pipeline TAGs

ID	Label	Description / generation	Pixel extraction	DPCM decode	DPCM encode	Pixel packing	Video Port	BYS Port	WRITE DMA
0	IDLE	Indicates no active data in the pipeline. Used to gate processing logic and save power	idle	idle	idle	idle	idle	idle	idle
1	ATT_HDR_S	Attribute header (bytes 0~7)	bypass	bypass	bypass	bypass	idle	idle	reset + write
2	ATT_HDR_E	Attribute header (bytes 8~15)	bypass	bypass	bypass	bypass	idle	idle	write + flush

cam_009

NOTE: Figure 9-10 does not describe all possible configurations for the CAL pixel processing stages. Depending on the use case, each pixel processing stage (extraction, DPCM decoding/encoding, packing) can be individually configured or bypassed via a dedicated bit-field in the `CAL_PIX_PROC_i` register.

9.2.3.2 CAL Hardware and Software Reset

An active low asynchronous hardware reset is provided by the ISS. It is internally resynchronized to the functional clock domain.

A software reset is triggered by setting the `CAL_HL_SYSCONFIG[0]` `SOFTRESET` bit to 0x1. The CAL hardware ensures that the software reset is performed on clean OCP transactions boundaries and that no OCP protocol violation can occur due to the software reset. Mainly, it finishes ongoing OCP transactions and prevents generation of new ones.

The `CAL_HL_SYSCONFIG[0]` `SOFTRESET` bit is automatically cleared by hardware when the software reset has completed. The software reset will never complete, if outstanding OCP responses are not returned. This situation is only expected when the slave with which CAL is communicating fails. A hardware reset is reset in that case.

A software reset is faster than a hardware reset controlled by the device PRCM module. In fact, to avoid OCP protocol violations, the PRCM module first puts the CAL into Idle mode. The PRCM can only perform a clean hardware reset once CAL has acknowledged the IDLE request. That only happens once the CAL has flushed all pending traffic and completed ongoing frames on the `RD_DMA`. A software reset simply waits for the next clean OCP transaction boundary without finishing the frame.

OCPC is fully functional after a software reset.

9.2.3.3 CAL Clock Configuration

CAL receives one functional clock from ISS that is also used for the OCP ports. The configuration port (OCPC) operates at half the functional clock speed (clock enable signal used).

9.2.3.4 CAL Power Management

CAL supports a IDLE protocol interface. It is used to ensure that the CAL clock / power can only be cut where there are no pending transactions. It is also used to ensure that CAL generates no more traffic before gating the functional clock. ISS sends an IDLE request to the CAL when the software requests CAL shutdown.

When CAL receives an IDLE request, it performs the following actions:

1. Finishes pending transactions:
 - a. All expected data on the BYS input port has been received. CAL can only acknowledge an IDLE request after a VE pulse has been received on the BYS input port when it is active (CAL_BYS_CTRL1[31] BYSINEN bit = 0x1).
 - b. No more data needs to be fetched by the RD DMA block. It first reads the complete frame and processes all data before it can acknowledge an IDLE request.
 - c. All data has been flushed out from the write buffer.
2. Disconnects the OCPC and OCPO ports on clean transaction boundaries.
3. Acknowledges the IDLE request.

9.2.3.5 CAL Interrupt Events

This section describes the interrupt events that can trigger the CAL_B_IRQ signal (see also [Section 9.2.2.1, CAL Main Integration Attributes](#)). The CAL_B_IRQ is merged at ISS top level IRQ merger.

NOTE: The CAL does not provide an event to detect Attribute Payload data at low level protocol level. Attribute data can only be sent to memory and therefore software can use the IRQ_WDMA_START / END events detected by the WR_DMA block.

Table 9-85. CAL Write DMA Interrupt Events

Event	Description
IRQ_WDMA_STARTx x= [0 ... CAL_HL_HWINFO[18:13] WCTX - 1]	Frame start. Triggered by the write DMA when a data word tagged as ATT_HDR_S, ATT_DAT_S, CTRL_HDR_S, PIX_HDR_S or PIX_DAT_FS has been detected by the write DMA. Typically used by SW to detect when shadowed registers can be updated for the next frame. Refer to section Section 9.2.3.10, CAL Write DMA , for more details.
IRQ_WDMA_ENDx x= [0 ... CAL_HL_HWINFO[18:13] WCTX - 1]	Frame end. Triggered by the write DMA when the FE tag has been received by the cropping stage and the last data of the last line has been sent to memory. Therefore, this event may be triggered after the last data has been written to memory when data has been discarded by the cropping feature. The FE corresponds to a data word tagged as ATT_HDR_E, ATT_DAT_E, CTRL_HDR_E, PIX_HDR_E, PIX_DAT_FE or FE_CODE. Typically used by SW to detect when all data of a header, attribute packet, control packet or pixel frame has been written to memory. This event is triggered when the last OCP transaction has been sent to memory but before the response for this OCP transaction has been received from the target. Therefore, there is a small delay between the moment where the event is triggered and the last data can be read back from the buffer. Typically that delay is compensated by IRQ detection latencies.
IRQ_WDMA_CIRCx x= [0 ... CAL_HL_HWINFO[18:13] WCTX - 1]	Circular event. Triggered when the number of lines defined by CAL_WR_DMA_OFST_k[23:22] CIRC_MODE has been sent to the OCP master port.

Table 9-86. CAL Read DMA Interrupt Events

Event	Description
IRQ_RDMA_END	The RD_DMA has read a complete frame and send all data to the CAL processing pipeline. This event is triggered when data has been sent to the processing pipeline, not when it is fully processed and sent to memory / BYS port / video port.

Table 9-86. CAL Read DMA Interrupt Events (continued)

Event	Description
IRQ_RDMA_CIRC	Circular event. Triggered when the number of lines defined by CAL_RD_DMA_CTRL2[2:0] CIRC_MODE register bit-field has been received from the OCP master port.

Table 9-87. CAL Line Number Interrupt Event

Event	Description
IRQ_LINE_NUMBER	Line number reached. The line number programmed in CAL_LINE_NUMBER_EVT[29:16] LINE register bit-field) is received on CPORT # CAL_LINE_NUMBER_EVT[4:0] CPORT.

Table 9-88. CAL Video Port EOF Interrupt Event

Event	Description
IRQ_VPORT_EOF	Event triggered when data tagged as PIX_DAT_FE is sent to the video port. Typically used by SW to detect when all data has been sent to the video port.

Table 9-89. CAL BYS Ports Interrupt Events

Event	Description
IRQ_BYSOUT_EOF	Event triggered when data tagged as PIX_DAT_FE are sent to the BYS output port. Typically used by software to detect when all data has been sent to the BYS output port.
IRQ_BYSOUT_VBLANK_END	Event triggered when the BYS output port finishes generation of the vertical blanking.
IRQ_BYSIN_SOF	Event triggered when data tagged as PIX_DAT_FS are received on the BYS input port. Typically used by software to detect when a new frame is received on the BYS input port.
IRQ_BYSIN_EOF	Event triggered when data tagged as PIX_DAT_FE are received on the BYS input port. Typically used by software to detect when all data has been received on BYS input port.
IRQ_BYSIN_OVR	Data has been discarded on the BYS input port because it has arrived at a faster rate than what the video port and/or the Write DMA can handle. That issue occurs when the video port pixel clock is lower than the pixel clock from the BYS input port or the WR_DMA buffer is full because of long latencies on OCPO.

DAT_PIX_FS and DAT_PIX_LS tags reset the pixel extraction state-machine. That ensures proper recovery in case the pixel decoder goes out of sync for some reason (for example, TxBuffer overflow in the transmitter, wrong configuration, bad synchronization between hardware and software).

Four samples do not necessarily align with a complete 64-bit word and several bits remain unused. They are stored locally until enough data is available to extract four additional samples or the end of a line has been reached (that is, TAG = PIX_DAT_LE or PIX_DAT_FE). The last 64-bit word can be padded with 0's, if there is not enough data to generate 4 pixels after all data tagged as PIX_DAT_LE or PIX_DAT_FE has been processed.

The incoming dataflow (from Read DMA) can be stalled to prevent data corruption:

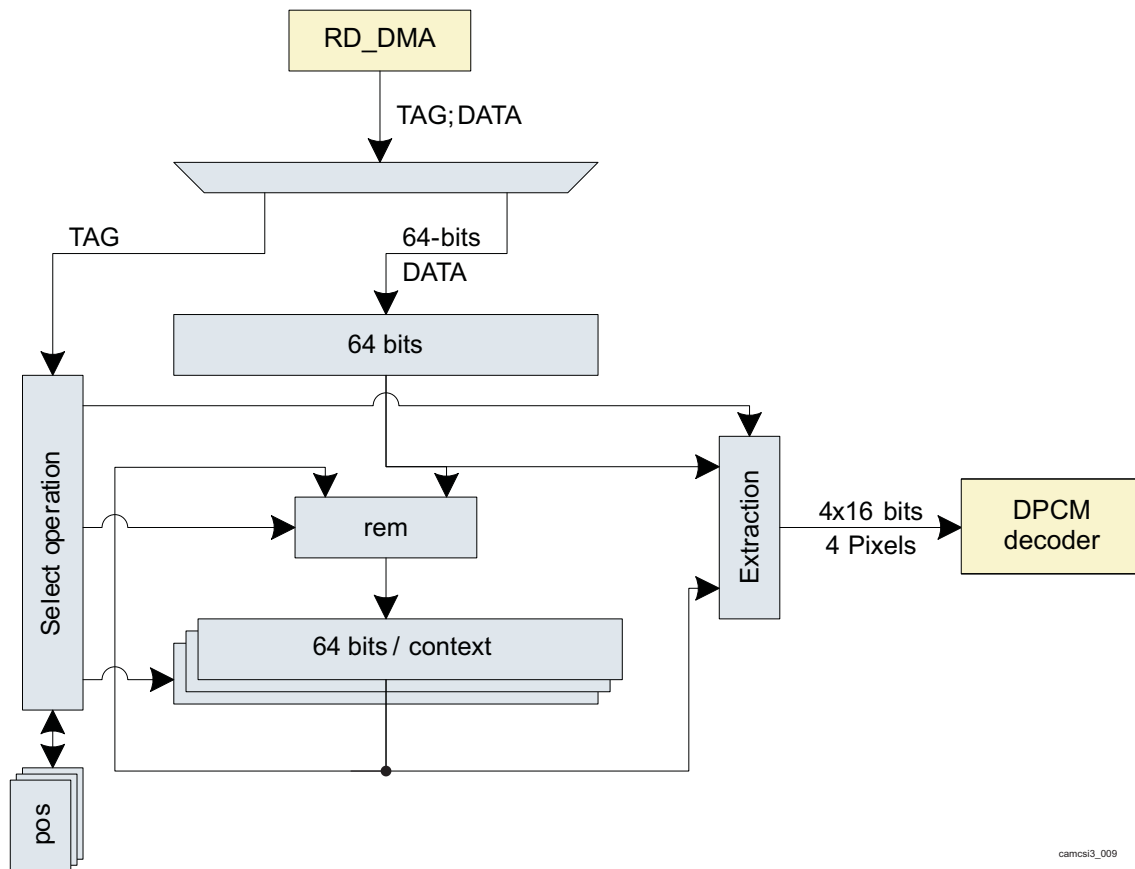

- When downstream modules cannot accept the data (that is, back-pressure from DPCM decoder)
- The extraction engine can only extract up to 4 pixels / cycle or forward complete 64-bit words without processing

Contexts can be interleaved with 64-bit word granularity (that is, two consecutive words can have different TAGs).

The number of contexts is as defined in the CAL_HL_HWINFO[12:8] PCTX register bit-field

Figure 9-12 shows the internal architecture of the pixel extraction module. It is composed of a 64-bit input buffer plus one 64-bit buffer per context (the number of contexts is as defined in the CAL_HL_HWINFO[12:8] PCTX register bit-field). It has two computation units that extract four pixels per cycle and return the unused bits into the local storage.

Figure 9-12. CAL Pixel Extraction

NOTE: The pixel extraction engine does not process the VQ (data validity qualifier). It forwards the VQ when bypass mode is selected and replaces it by VQ=0 (all data valid) when data expansion is performed.

9.2.3.8 CAL DPCM Decoding and Encoding

The CAL DPCM decoder block only processes data tagged as DAT_PIX_FS, DAT_PIX_LS, DAT_PIX, DAT_PIX_LE and DAT_PIX_FE (as defined in [Figure 9-10, CAL Data Pipeline TAGs](#)). All other data types or data belonging to CPORTs, where DPCM encode/decode is disabled, is simply forwarded. Software selects which CPORT a given pixel processing context must process by setting the [CAL_PIX_PROC_i\[23:19\]](#) CPORT register bit-field to the CPORT ID. The DPCM decompression operation is selected through the [CAL_PIX_PROC_i\[9:5\]](#) DPCMD bit-field, and the DPCM compression operation is selected through the [CAL_PIX_PROC_i\[15:11\]](#) DPCME bit-field.

PIX_DAT_FS and PIX_DAT_LS tags initialize the DPCM encoder.

PIX_DAT_FS and PIX_DAT_LS tags initialize the DPCM decoder, except when the previous TAG received on that context was DPCM_INIT. DPCM_INIT copies the received word into the context status register of the DPCM decoder and discards the initialization word (that is, it is not forwarded to the next pipeline stage). The next word of four pixels received on that context is DPCM decoded and the usual initialization step is skipped. That feature is intended to enable DPCM decoding of an image in multiple vertical stripes without re-decoding each line from the beginning (see [Section 9.2.3.8.1](#), for more details).

Table 9-90. CAL DPCM Formats

Codec	Predictor	Decode	Encode	Performance
10 - 8 - 10	Predictor 1	YES	YES	4 px/cyc
10 - 8 - 10	Predictor 2			
10 - 7 - 10	Predictor 1	YES		4 px/cyc
10 - 7 - 10	Predictor 2	YES		1 px/cyc
10 - 6 - 10	Predictor 1	YES		4 px/cyc
10 - 6 - 10	Predictor 2	YES		1 px/cyc
12 - 8 - 12	Predictor 1	YES	YES	4 px/cyc
12 - 8 - 12	Predictor 2			
12 - 7 - 12	Predictor 1	YES		4 px/cyc
12 - 7 - 12	Predictor 2			
12 - 6 - 12	Predictor 1	YES		4 px/cyc
12 - 6 - 12	Predictor 2			
14 - 10 - 14	Predictor 1	YES	YES	4 px/cyc
14 - 10 - 14	Predictor 2			
14 - 8 - 14	Predictor 1	YES	YES	4 px/cyc
14 - 8 - 14	Predictor 2			
16 - 12 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 12 - 16	Predictor 2			
16 - 10 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 10 - 16	Predictor 2			
16 - 8 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 8 - 16	Predictor 2			

The DPCM encoder and decoder are independent. They preserve state for each of the pixel processing contexts (number defined in [CAL_HL_HWINFO\[12:8\]](#) PCTX register bit-field), so that the encoder and the decoder context can be swapped with 4-pixel granularity.

The DPCM encoder and decoder can stall the incoming pixel from the pixel extraction block, if it arrives faster than what they can handle (that is, PREDICTOR2 selection or dataflow stalled by the pixel packing stage/write DMA).

9.2.3.8.1 CAL Partial DPCM Decompression

CAL supports DPCM decompression of a complete image in vertical stripes (i.e. frame division mode). This feature is typically used to provide decompressed to hardware that operates in frame division mode and that has to operate from a full frame DPCM compressed buffer. Stripes can overlap to compensate to filtering overlap.

First stripe configuration:

- Configure the RD_DMA to "n" pixels per line.
- Configure one WR_DMA context to send at least 4 pixels per line to SDRAM that will be used to resume DPCM decompression on the next stripe.
- Configure one pixel processing context for DPCM decompression (normal mode).
- Configure BYS ports, video port and/or WR_DMA to send decompressed pixels to the destination.

Other stripes configuration:

- Configure the RD_DMA to "n" pixels per line and to read 4 pixels of initialization data per line.
- Configure one WR_DMA context to send at least 4 pixels per line to SDRAM that will be used to resume DPCM decompression on the next stripe (not needed for the last stripe).
- Configure one pixel processing context for DPCM decompression (resume mode).
- Configure BYS ports, video port, and/or WR_DMA to send decompressed pixels to the destination.

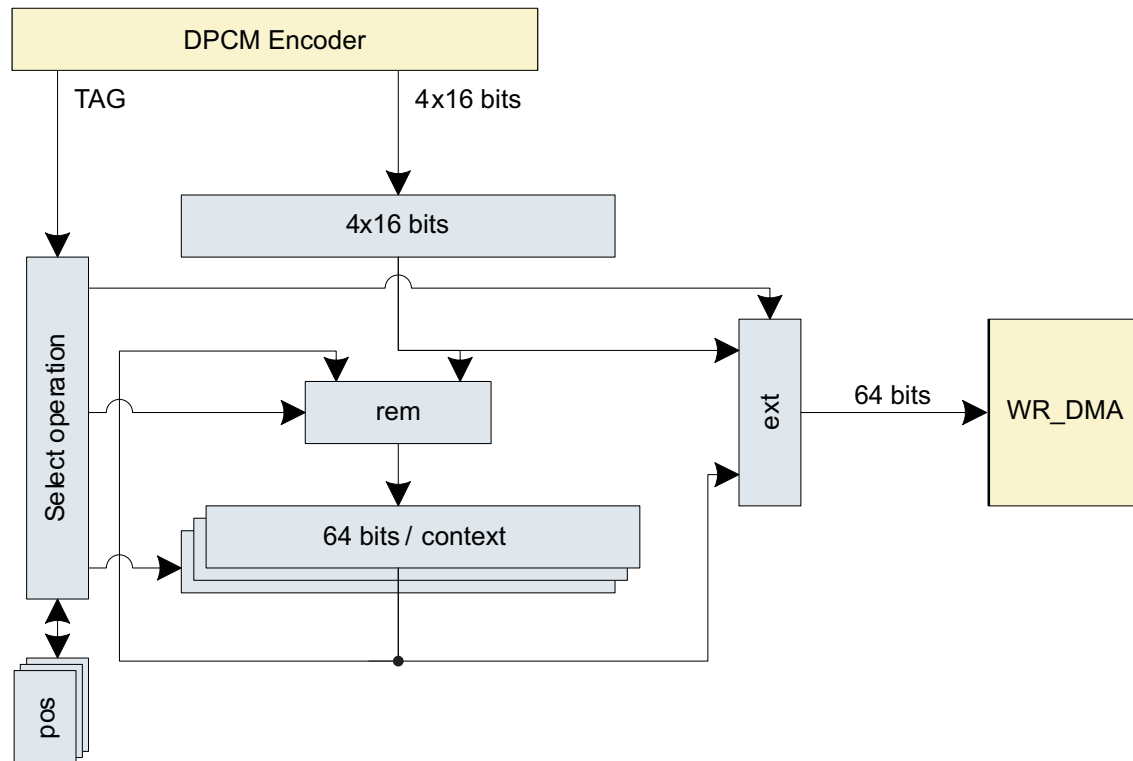

9.2.3.9 CAL Pixel Packing

Software selects which CPORT a given pixel processing context must process by setting the [CAL_PIX_PROC_i\[23:19\]](#) CPORT bit field to the CPORT ID. The operation to perform is defined by the [CAL_PIX_PROC_i\[18:16\]](#) PACK bit field.

The pixel packing stage only processes data tagged as PIX_DAT_FS, PIX_DAT_LS, PIX_DAT, PIX_DAT_FE and PIX_DAT_LE. All other data types or data belonging to a C-Port where pixel packing is disabled is simply forwarded. The packing stage is reset by PIX_DAT_FS and PIX_DAT_LS to recover synchronization in case it has been lost.

The pixel packing stage is flushed by a PIX_DAT_FE, PIX_DAT_LE and PIX_DAT_LE TAG: the last generated 64-bit word may be padded with 0's

Pixel packing is a symmetrical processing step to the pixel extraction (see [Section 9.2.3.7](#), *CAL Pixel Extraction*). However, the list of supported formats is different. The pixel packing stage also has buffering to preserve temporary (that is, incomplete) data when contexts are switched. [Figure 9-13](#) below shows the internal architecture of the packing stage.

Figure 9-13. CAL Pixel Packing

camcsi2_010

Supported packing modes are:

- RAW8 (8 bits per pixel)
- RAW10 (MIPI) (10 bits per pixel)
- RAW12 (linear) (12 bits per pixel)
- RAW12 (MIPI) (12 bits per pixel)
- RAW16 (16 bits per pixel)
- ARGB (32 bits per pixel)

The pixel packing engine does not process the VQ (data validity qualifier). It forwards the VQ when bypass mode is selected and replaces it by VQ=0 (all data valid) when data expansion is performed.

Figure 9-14 shows how the packing engine packs 32 consecutive pixels (equal to 8 active input cycles as 4 pixels are provided per cycle) into five 64-bit words ready to be sent to memory (REM).

Figure 9-14. CAL MIPI RAW10 Data Packing

camcs12-011

Figure 9-15 shows how the packing engine packs consecutive pixels (Px corresponds to a 16-bit pixel in the internal pipeline) into 64-bit words.

9.2.3.10 CAL Write DMA

9.2.3.10.1 CAL Write DMA Overview

The memory write DMA has a number of WCTX (defined in [CAL_HL_HWINFO\[18:13\]](#) WCTX register bit-field) independent write contexts (that is, logical DMA channels). Each context receives a byte stream over a 64-bit wide bus as well as the TAG.

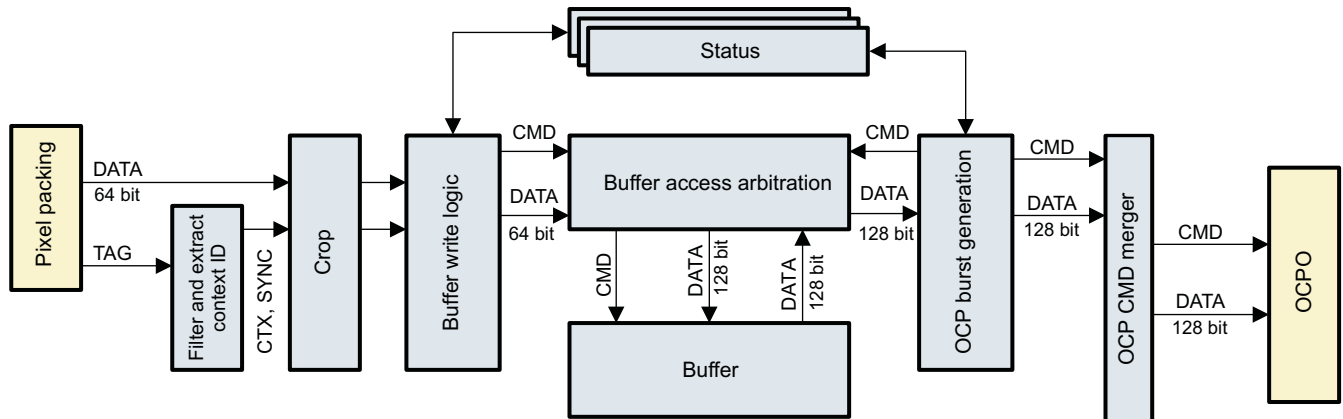

The write DMA filters incoming data using the CPORT number and data type contained in the TAG. Data is only processed, if it matches the CPORT number defined in the [CAL_WR_DMA_CTRL_k\[13:9\]](#) CPORT register bit-field and the data type defined in the [CAL_WR_DMA_CTRL_k\[8:6\]](#) DTAG bit-field. It also uses the received TAG to lookup the adequate context information and control the address generation logic.

Only one write context can process a given data word from the internal pipeline at the time. Said differently, the write DMA cannot be used to write two copies of the same data into separate locations. Software must prevent that two active write contexts have the same settings for [CAL_WR_DMA_CTRL_k\[13:9\]](#) CPORT and [CAL_WR_DMA_CTRL_k\[8:6\]](#) DTAG bit-fields.

Data that is not processed by the write DMA is discarded. Since the write DMA is the last stage in the CAL processing pipeline, it does not forward data to a next stage.

Figure 9-16 shows a simplified block diagram of the write DMA engine.

Figure 9-16. CAL Write DMA Block Diagram

cam_020

9.2.3.10.2 CAL Write DMA Data Cropping

It is possible to discard part of the received data for pixel and attribute data (that is, header and control data cannot be discarded). This is performed inside the write DMA cropping block. The feature is enabled by configuring:

- The position of the 1st byte to preserve in each line in the `CAL_WR_DMA_XSIZE_k[15:3]` XSKIP register bit-field
- The number of bytes to preserve for each line in the `CAL_WR_DMA_XSIZE_k[31:19]` XSIZE bit-field

The cropping block discards unwanted data and modifies data TAG to preserve integrity. For example, when pixel data is processed:

- PIX_DAT_FS => 1st word of a frame
- PIX_DAT_LS => 1st word of a line, except for the 1st line
- PIX_DAT_LE => last word of a line, except for the last line
- PIX_DAT_FE => last word of a frame
- PIX_DAT => any other pixel data

Cropping is mainly intended to enable partial DPCM decompression and to reduce storage requirements / power consumption when digital zoom is used. No dummy data will be written, if the programmed size is less than what is received. Refer to [Section 9.2.3.8.1, CAL Partial DPCM Decompression](#), for more details.

Cropping may also be used for attribute data. It cannot be used for header data. It is SW responsibility to not use cropping for header data. HW does not perform any additional checks.

The DMA accumulates data independently for contexts until an OCP write transaction can be generated. That is the case when enough data is available to generate a full burst or when the end of an image line has been reached.

NOTE: Data cropping is performed after the DPCM encoder. Therefore, horizontal skipping cannot be used when data is DPCM encoded. Otherwise, it will be not possible to decode the data, unless reference samples have been stored to resume decode.

9.2.3.10.3 CAL Write DMA Buffer Management

The DMA write buffer has two functions:

- Accumulate enough data to issue efficient OCP transactions
- Buffer data when it cannot be written to the OCPO port

Different write contexts do not have fixed locations in the write buffer to optimize the required buffer size. In fact, at a given point of time only some of the contexts are active while others are idle. There is no reserved space for unused contexts. Also, different contexts have different bandwidth requirements. Therefore, different amounts of data will pile up for different contexts when OCPO is stalled.

The buffer is divided into slots of $2^{(WDMA_SLOTSIZE+7)}$ bytes that are dynamically allocated to a context. CAL maintains some internal status information to manage the buffer:

- For each slot:
 - State (2 bits):
 - Empty
 - Open (ready to receive more data)
 - Closed (does not accept new data; ready for OCP burst generation)
 - Level (4 bits): amount of data currently stored in the data slot
 - Cleared when data has been sent to OCPO
 - Incremented by 8 bytes each time a new word of 64-bits is added
 - Destination Address (29 bits): destination address for an OCP burst
 - This value is computed when the 1st word of 64-bits is stored in the slot
 - All data of the slot is stored contiguously in memory. The HW allocates new slots to skip memory locations at line ends.
- For each context
 - Slot current in use (if applicable)
 - Destination address

The write DMA uses the data qualifier provided along with data words to pack data in the local working memory. It has a barrel shifter to pack data when lines ends do not correspond to 64-bit word boundaries.

OCP bursts cannot span over multiple slots for design simplification. Refer to [Section 9.2.3.10.5, CAL Write DMA OCP Transaction Generation](#), for more details.

9.2.3.10.4 CAL Write DMA OCP Address Generation

NOTE: CAL can perform Tiler view memory access by configuring CTRL_CORE_SMA_SW_3[30] CAL_TILED_MEMORY_SPACE register bit. For more details, refer to [Section 2.2, L3_MAIN Memory Space Mapping](#), and [Chapter 20, Control Module](#).

9.2.3.10.4.1 Write DMA Buffer Base Address

The buffer base address (referred to as BASE, internal variable that cannot be read by SW) is automatically updated when an ATT_HDR_S, ATT_DAT_S, CTRL_HDR_S, PIX_HDR_S or PIX_DAT_FS is received by the write DMA using the following algorithm based around CAL_WR_DMA_CTRL_k[2:0] MODE register bit-field:

- MODE = 0x0 (Disable): DMA is disabled
- MODE = 0x1 (Ping/pong destination address on every frame):
 - BASE = CAL_WR_DMA_ADDR_k
 - CAL_WR_DMA_ADDR_k = CAL_WR_DMA_ADDR_OLD
 - CAL_WR_DMA_ADDR_OLD = BASE
- MODE = 0x3 (Initialize start address for continuous mode. The first frame will be written at this address and consecutive frames will be appended):
 - BASE = CAL_WR_DMA_ADDR_k
 - CAL_WR_DMA_ADDR_k = CAL_WR_DMA_ADDR_OLD

- CAL_WR_DMA_ADDR_OLD = LINE_START (See [Section 9.2.3.10.4.2, Write DMA Line Start Address](#), for further details)
- CAL_WR_DMA_CTRL_k[2:0] MODE = 0x2
- MODE = 0x2 (Continuously write data to memory):
 - BASE = LINE_START + CAL_WR_DMA_OFST_k
- MODE = 0x4 (Use CAL_WR_DMA_ADDR_k as base address)
 - BASE = CAL_WR_DMA_ADDR_k

After reset, CAL_WR_DMA_ADDR_OLD = 0x00000000. Software must update the CAL_WR_DMA_ADDR_k register after the first FE event with a valid destination address. Otherwise, data will be sent to address 0 which is typically not a valid destination.

9.2.3.10.4.2 Write DMA Line Start Address

The line start address is set to the base address when the base address is updated (that is, LINE_NUMBER = 0 at frame start). Otherwise, the line start address is updated upon reception of the PIX_DAT_LS tag depending on the CAL_WR_DMA_OFST_k[23:22] CIRC_MODE register bit-field and CAL_WR_DMA_CTRL_k[4:3] WR_PATTERN bit-field. [Table 9-91](#) summarizes how the line starts address (LINE_START) and line numbers are updated on every PIX_DAT_LS tag.

Table 9-91. Write DMA - Line Start Address Computation

CAL_WR_DMA_OFST_k [23:22] CIRC_MODE	CAL_WR_DMA_CTRL_k [4:3] WR_PATTERN	Description
0 (Disabled)	0 (Linear)	Linear buffer LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST
0 (Disabled)	2 (Write 2 lines, skip 2 lines)	Linear buffer + skip pattern if LINE_N #2 == 0: LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST else: LINE_N = LINE_N + 3 LINE_START = LINE_START + 3*CAL_WR_DMA_OFST_k[18:4] OFST
0 (Disabled)	3 (Write 2 lines, skip 4 lines)	Linear buffer + skip pattern if LINE_N #2 == 0: LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST else: LINE_N = LINE_N + 5 LINE_START = LINE_START + 5*CAL_WR_DMA_OFST_k[18:4] OFST
1 (1 Line) 2 (4 Lines) 3 (64 Lines)	0 (Linear)	Circular buffer if CIRC_MODE == 1: G = 1 elif CIRC_MODE == 2: G = 4 else: G = 64 if LINE_N == G*CAL_WR_DMA_OFST_k[31:24] CIRC_SIZE: LINE_N = 0 LINE_START = BASE else: LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST
different than 0	different than 0	Reserved. Do not use this combination.

NOTE: `CAL_WR_DMA_CTRL_k[2:0]` MODE must be set to 0x0 (disabled) or 0x4 (use `CAL_WR_DMA_ADDR_k` as base address), when `CAL_WR_DMA_OFST_k[23:22]` CIRC_MODE !=0.

9.2.3.10.4.3 Write DMA Data Address

Data received together with the ATT_HDR_S, ATT_DAT_S, CTRL_HDR_S, PIX_HDR_S, PIX_DAT_FS or PIX_DAT_LS tag is stored at the line start address (refer to [Section 9.2.3.10.4.2, Write DMA Line Start Address](#)). For all other tags (ATT_HDR_E, ATT_DAT, ATT_DAT_E, PIX_HDR_E, CTRL_HDR_E, PIX_DAT, PIX_DAT_FE or PIX_DAT_LE), data is appended (that is, ADDR+ = 8, for each word of 64-bits).

[Figure 9-17](#) illustrates how data is stored in memory when `CAL_WR_DMA_OFST_k[23:22]` CIRC_MODE = 0 (disabled) and `CAL_WR_DMA_CTRL_k[4:3]` WR_PATTERN = 0 (linear).

The write DMA channel with the lowest ID has the highest priority when multiple channels are ready to send data simultaneously.

Software can use `CAL_WR_DMA_XSIZE_k[31:19]` XSIZE = 0 in case the stream size is not known or exceeds the maximum range of the XSIZE bitfield. CAL skips the cropping feature in that case and sends all data to memory. However, software must still ensure that enough memory space has been allocated.

9.2.3.10.5 CAL Write DMA OCP Transaction Generation

The write DMA generates OCP write bursts of 1–8 x 16 bytes. A burst never crosses a 128 byte boundary. The maximum burst size is defined by the `CAL_CTRL[6:5]` BURSTSIZE register bit-field. The first and the last burst of a contiguous data block may use smaller burst sizes than defined in the BURSTSIZE bit-field. Bursts in the middle of the data block must use exactly the size defined in the BURSTSIZE bit-field.

9.2.3.10.6 CAL Write DMA Real Time Traffic

Data traffic for which the pixel rate is imposed by a camera interface is qualified as a hard real time traffic. Such data, once received, can be optionally processed in the CAL and then sent to SDRAM using the OCPO port.

Hard real time traffic cannot be stalled for long periods of time. Indeed, when data is sent at constant speed it can only be stalled until FIFOs on the path are filled up. When FIFOs become full, data is discarded and the frame is therefore corrupted. To minimize the risk of real time data corruption, the device supports a mechanism that is activated by the MFlag generated by real time initiators.

MFlag generation must be disabled (through `CAL_CTRL[20:13]` MFLAGL = 0xFF and `CAL_CTRL[31:24]` MFLAGH = 0xFF), when CAL does not generate any real time traffic.

Static assertion of MFlag is only supported for debug purposes and must not be enabled for normal utilization (`CAL_CTRL[20:13] MFLAGL = 0x00 -> MFlag=0x11`; `CAL_CTRL[20:13] MFLAGL = 0xFF` and `CAL_CTRL[30:24] MFLAGH = 0x00 -> MFlag=0x01`).

Dynamic MFlag generation is to be used when the write DMA operates on real time data. In that case, the MFlag value depends on the number of slots (n) ready to generate transactions in the write DMA:

- MFlag = 00: SAFE ($n < \text{CAL_CTRL}[20:13] \text{MFLAGL}$)
- MFlag = 01: VULNERABLE ($\text{CAL_CTRL}[20:13] \text{MFLAGL} \leq n < \text{CAL_CTRL}[31:24] \text{MFLAGH}$)
- MFlag = 11: ENDANGERED ($\text{CAL_CTRL}[30:24] \text{MFLAGH} \leq n$)

Software must ensure that:

- $\text{CAL_CTRL}[20:13] \text{MFLAGL} \leq \text{CAL_CTRL}[30:24] \text{MFLAGH}$ (only 0x00 or 0x11 generated, when $\text{MFLAGL} = \text{MFLAGH}$)
- $\text{CAL_CTRL}[20:13] \text{MFLAGL} = 0x00, 0xFF$ or less or equal to $2^{(\text{CAL_HL_HWINFO}[3:0] \text{WFIFO} - 3)}$
- $\text{CAL_CTRL}[30:24] \text{MFLAGH} = 0x00, 0xFF$ or less or equal to $2^{(\text{CAL_HL_HWINFO}[3:0] \text{WFIFO} - 3)}$

Optionally, the traffic from the Read DMA to the internal CAL pipeline can be stalled when MFlag is non zero via the `CAL_CTRL[22] RD_DMA_STALL` register bit. That mechanism shall be enabled when data read by the RD DMA translates into data written by the WR DMA (for example, RD DMA -> BYSSout -> BYSSin -> WR DMA). It avoids that FIFO slots continue to be filled up with non real time data when the WR FIFO reaches a critical level.

9.2.3.11 CAL Read DMA

9.2.3.11.1 CAL Read DMA Overview

The read DMA is used to read pixel data from SDRAM and send it through the CAL processing pipeline. [Table 9-92](#) summarizes the mode combinations supported:

Table 9-92. CAL Read DMA Mode Supported Combinations

CIRC_MODE	RD_PATTERN	INIT	Description
0	LINEAR	0	Raster data from a single buffer
0	YUV420	0	YUV420 data from a two buffers
0	RD2SKIP2	0	Raster data from a single buffer with skip pattern
0	RD2SKIP4	0	Raster data from a single buffer with skip pattern
0	LINEAR	1	Raster data from a single buffer + DPCM initialization
0	YUV420	1	reserved.
0	RD2SKIP2	1	Raster data from a single buffer + skip pattern + DPCM initialization
0	RD2SKIP4	1	Raster data from a single buffer + skip pattern + DPCM initialization
>0	LINEAR	0	Raster data from a circular buffer
>0	YUV420	0	YUV420 data from a two circular buffers
>0	RD2SKIP2	0	reserved.
>0	RD2SKIP4	0	reserved.
>0	LINEAR	1	reserved.
>0	YUV420	1	reserved.
>0	RD2SKIP2	1	reserved.
>0	RD2SKIP4	1	reserved.

The read DMA fetches one to two streams simultaneously, depending on the chosen mode. Circular addressing and line skip patterns for both streams use the same algorithm than the write DMA (see [Section 9.2.3.10](#))

Reading of initialization data is optional and should be enabled before the read DMA is started by setting the `CAL_RD_DMA_CTRL[1]` INIT bit.

The read DMA is enabled by setting the `CAL_RD_DMA_CTRL[0]` GO bit. It sends the amount of data defined by configuration through the processing pipeline, triggers an `IRQ_RDMA_END` event and then returns into idle state until it is enabled again by SW.

9.2.3.11.2 CAL Read DMA Data Provided to Processing Pipeline

The read DMA generates adequate TAGs for proper control of the processing pipeline. It always uses the CPORT ID #0.

[Table 9-93](#) shows how data is sent through the CAL processing pipeline after it has been read from memory.

Table 9-93. CAL Read DMA Data

BUFF	POS X	POS Y	Read ADDR	SIZE	TAG
INIT		0	<code>CAL_RD_DMA_INIT_ADDR + 0 *</code> <code>CAL_RD_DMA_INIT_OFST</code>	8	DPCM_INIT
PIX	0	0	<code>CAL_RD_DMA_PIX_ADDR + 0 *</code> <code>CAL_RD_DMA_PIX_OFST + 0</code>	8	PIX_DAT_FS

INIT		2	<code>CAL_RD_DMA_INIT_ADDR + 2 *</code> <code>CAL_RD_DMA_INIT_OFST</code>	8	DPCM_INIT
PIX	0	2	<code>CAL_RD_DMA_PIX_ADDR + 2 *</code> <code>CAL_RD_DMA_PIX_OFST + 0</code>	8	PIX_DAT_LS
INIT		(YSIZE-1)	<code>CAL_RD_DMA_INIT_ADDR + (YSIZE-1) *</code> <code>CAL_RD_DMA_INIT_OFST</code>	8	DPCM_INIT
PIX	0	(YSIZE-1)	<code>CAL_RD_DMA_PIX_ADDR + (YSIZE-1) *</code> <code>CAL_RD_DMA_PIX_OFST + 0</code>	8	PIX_DAT_LS
PIX	8	(YSIZE-1)	<code>CAL_RD_DMA_PIX_ADDR + (YSIZE-1) *</code> <code>CAL_RD_DMA_PIX_OFST + 8</code>	8	PIX_DAT
PIX	16	(YSIZE-1)	<code>CAL_RD_DMA_PIX_ADDR + (YSIZE-1) *</code> <code>CAL_RD_DMA_PIX_OFST + 16</code>	8	PIX_DAT
PIX	(XSIZE-8)	(YSIZE-1)	<code>CAL_RD_DMA_PIX_ADDR + (YSIZE-1) *</code> <code>CAL_RD_DMA_PIX_OFST + (XSIZE-8)</code>	8	PIX_DAT_FE

9.2.3.11.3 CAL Read DMA Skipping Modes

CAL supports 2 line skipping read patterns. Those are mainly intended to provide vertically sub-sampled images. SW shall adjust the SDRAM start address to select the correct sub-sampled phase (that is, +0 and +2 lines in RD2SKIP2 mode; and +0, +2 and +4 lines in RD2SKIP4 mode). [CAL_RD_DMA_YSIZE](#) indicates the number of lines to read from SDRAM. It does therefore not include skipped lines.

9.2.3.11.4 CAL Read DMA YUV420 Support

CAL reads YUV420 NV12 or NV21 data from memory when `CAL_RD_DMA_CTRL2[5:4] RD_PATTERN = YUV420`. UV data is read twice and interleaved at byte level with Y data to provide YUV422 UYVY to the internal pipeline. The image size read from memory is `CAL_RD_DMA_XSIZE .XSIZE*8 bytes x CAL_RD_DMA_YSIZE .YSIZE lines` for the Y buffer, and `CAL_RD_DMA_XSIZE .XSIZE*8 bytes x CAL_RD_DMA_YSIZE .YSIZE/2 lines` for the UV buffer. However, each UV line is read twice. The image size provided to the internal pipeline is `CAL_RD_DMA_XSIZE .XSIZE*16 bytes x CAL_RD_DMA_YSIZE .YSIZE lines`.

Figure 9-21. CAL Read DMA YUV420 Upsampling

cam_025

NOTE: CAL duplicates chrominance data and does not interpolate it.

Circular mode can be combined with YUV420 upsampling. The spatial wrap point is the same for the Y and UV planes and UV lines are still read twice.

Figure 9-22. CAL Read DMA YUV420 Upsampling in Circular Mode

cam_026

9.2.3.11.5 CAL Read DMA OCP Request Generation

The OCP request generation state machine loops through the phases described below for each image line until the complete image has been fetched.

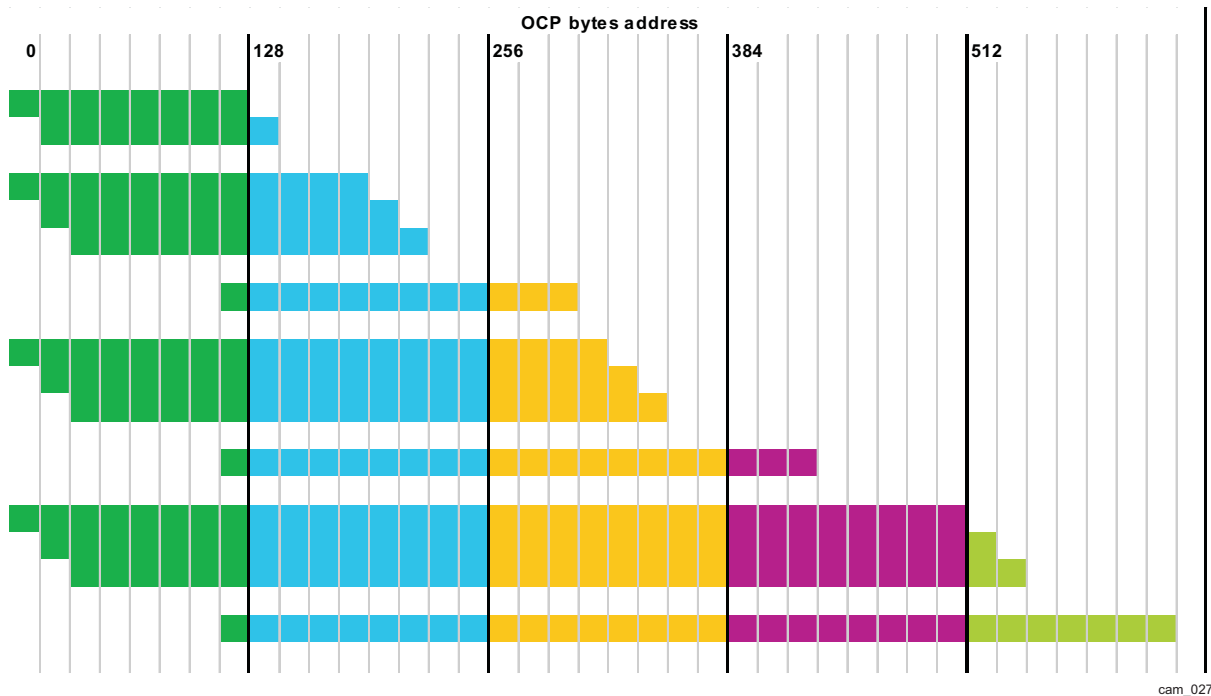

- DPCM initialization data
 - [CAL_RD_DMA_CTRL](#) .INIT=1
 - Initialization data fetched as single request of 16 bytes
 - The source address must be 8 byte aligned. The RD DMA fetches 16 bytes (full OCP bus width) but only uses 8 of them (depending on bit 3 of the data fetch address)
 - [CAL_RD_DMA_CTRL](#) .INIT=0
 - This step is skipped
- Pixel data / Y data / UV data
 - When [CAL_RD_DMA_CTRL](#) .RD_PATTERN=YUV420, requests for Y and UV are interleaved at OCP burst boundary. Both streams share the same response FIFO and data is interleaved before sending it to the internal pipeline.
 - One ([CAL_RD_DMA_CTRL](#) .RD_PATTERN /= YUV420) or two ([CAL_RD_DMA_CTRL](#) .RD_PATTERN=YUV420) smaller burst(s) is (are) issued to re-align OCP address to the burst boundary (defined by [CAL_CTRL](#) .BURST_SIZE)
 - "n" full sized bursts (defined by [CAL_CTRL](#) .BURST_SIZE) are issued to fetch the data in the

middle of the line

- One (`CAL_RD_DMA_CTRL .RD_PATTERN/=YUV420`) or two (`CAL_RD_DMA_CTRL .RD_PATTERN=YUV420`) smaller burst(s) is (are) issued to fetch the remaining data at the line end (burst size is less than `CAL_CTRL .BURST_SIZE`).
- An OCP can never cross a 128 byte boundary or be longer than the size define in `CAL_CTRL .BURST_SIZE`

Figure 9-23 shows a few graphical examples of OCP burst generation for pixel data.

Figure 9-23. CAL Read DMA OCP Request Generation for Pixel Data

Below is an example sequence of OCP transactions.

Parameters

`CAL_CTRL .BURST_SIZE = 128`

`CAL_RD_DMA_INIT_ADDR = 0x00100020`

`CAL_RD_DMA_INIT_OFST = 0x00000008`

`CAL_RD_DMA_PIX_ADDR = 0x000027C0`

`CAL_RD_DMA_PIX_OFST = 0x000003E0`

`CAL_RD_DMA_XSIZE = 816`

`CAL_RD_DMA_YSIZE = 10`

cam_028

The read DMA pipelines requests to OCPO for best performance. It has a FIFO to store prefetched data until it can be sent through the processing pipeline. It requests new data from SDRAM until the complete frame has been read. Requests can only be issued when:

- There is enough space in the FIFO to store the OCPO response
- OCPO is idle (i.e. write DMA requests have higher priority)
- No more than [CAL_RD_DMA_CTRL.TAG_CNT](#) read requests are outstanding
- No more than [CAL_CTRL.TAG_CNT](#) read+write requests are outstanding (two separate configuration registers are provided so that a certain number of tags can be reserved exclusively for write transactions)
- The last read request was issues more than [CAL_RD_DMA_CTRL.BW_LIMITER*8](#) clock cycles ago.

The read FIFO can only hold data from up to two consecutive images lines and their initialization data. Performance will be lower for very "small" lines when OCP latencies are "long" as the read FIFO will not prefetch "enough" data. Full performance is expected for image lines wider than 512 bytes.

9.2.3.12 CAL Video Port

9.2.3.12.1 CAL Video Port Overview

Figure 9-25 shows the CAL video port internal architecture. It is composed of a timing generator and a FIFO.

The video port receives data + TAGs from the DPCM decoder stage. It filters the received data and only processes data that:

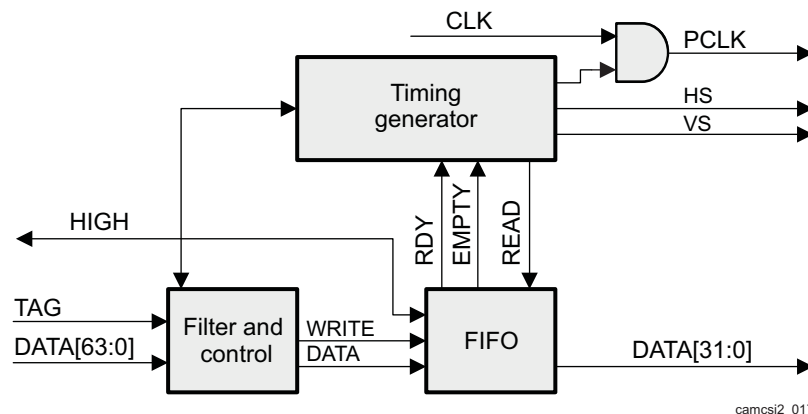

- Matches the CPORT ID defined by the `CAL_VPORT_CTRL2[4:0]` CPORT register bit-field
- Is tagged as `PIX_DAT_FS`, `PIX_DAT_LS`, `PIX_DAT`, `PIX_DAT_LE` or `PIX_DAT_FE`

In addition, it uses the `FE_CODE` tag to enter the vertical blanking period after the end of the horizontal blanking period when the vertical blanking period is not already started.

Other data is ignored by the video port (this does not affect the operation of other pipeline stages).

NOTE: Only one CPORT can use the video port and only pixel data can be sent to the video port (that is, control and attribute packets are ignored).

Figure 9-25. CAL Video Port and Timing Generator

The FIFO receives data from the internal processing pipeline at a variable rate (up to 4 pixels per cycle). The `HIGH` signal is asserted a few cycles before the FIFO becomes full. It is used to stall the incoming pixel flow (from the `RD_DMA`) at time. Therefore, no FIFO overflow can occur.

The timing generator is started after a `PIX_DAT_FS` tag, when the FIFO level exceeds the threshold defined in `CAL_VPORT_CTRL2[31:18]` `RDY_THR` bit field. This threshold is 0 by default but may be used to smooth the traffic on the video port.

The timing generator controls pixel reads from the FIFO. It only reads a pixel when:

- The current output position corresponds to an active location.
- Data is ready in the FIFO.

The video port is stalled when the `VP_STALL` signal is asserted. Data is buffered in the FIFO when data continues to arrive while the video port is stalled. Back pressure is propagated upstream by asserting the `HIGH` signal when the FIFO is full.

9.2.3.12.2 CAL Video Port Pixel Clock Generation

The video port pixel clock (VP_PCLK) is generated from the functional clock (CAL_FCLK). Software sets the peak pixel rate using the [CAL_VPORT_CTRL1\[16:0\] PCLK](#) register bit-field. The pixel rate is automatically controlled by the hardware, when data arrives from the RD_DMA.

The mean pixel clock rate on the video port can be given with the equation:

$$\text{VP_PCLK} = \text{CAL_FCLK} \times \text{CAL_VPORT_CTRL1[16:0] PCLK} / 65536$$

As VP_PCLK is generated from the CAL functional clock, some clock pulses are gated to reach the selected frequency. The following algorithm is used to generate the internal PCLK_EN signal:

1. ACC = [CAL_VPORT_CTRL1\[16:0\] PCLK](#)
2. If (ACC + [CAL_VPORT_CTRL1\[16:0\] PCLK](#) >= 65536) then PCLK_EN=1 else PCLK_EN=0
3. ACC = (ACC + [CAL_VPORT_CTRL1\[16:0\] PCLK](#)) % 65536
4. Go back to step #2

The configured pixel clock is used for active as well as for blanking periods.

9.2.3.12.3 CAL Video Port Video Timing Generator

The timing generator state-machine reuses the synchronization information received through TAGs to:

- Control state transitions
- Assert the VP_HS and VP_VS signals
- Detect when data is ready to be sent

For more details on the video port, refer to [Section 9.2.2.2, CAL Integration - Video Port](#).

The timing generator can be unconditionally reset in the following ways:

- A general hardware reset (by CAL_RST signal) or software reset (through the [CAL_HL_SYSCONFIG\[0\] SOFTRESET](#) register bit)
- Setting the [CAL_VPORT_CTRL2\[17\] FSM_RESET](#) bit

It is also reset by data tagged as PIX_DAT_FS when the [CAL_VPORT_CTRL2\[16\] FS_RESETS](#) bit is set. This bit is enabled by default, but may be disabled when vertical blanking times are very short and there is no risk of TX data dropping/desynchronizing.

Four VP_PCLK cycles are sent before the first active pixel. The video port state-machine then waits until four VP_PCLK cycles are sent after the last blanking cycle of the frame.

Active data is sent to the video port only when at least 4 × [CAL_VPORT_CTRL2\[31:18\] RDY_THR](#) pixels are available. That mechanism can be used to smooth the pixel rate on the video port, if input data arrives at bursty rate. The video port FIFO accumulates 4 × [CAL_VPORT_CTRL2\[31:18\] RDY_THR](#) after frame start before it sends the first pixel, and signal VP_VS = VP_HS = 1.

The video port can generate horizontal and vertical blanking in addition to pixels received from the CAL pipeline. The amount of blanking is defined by the [CAL_VPORT_CTRL1\[24:17\] XBLK](#) and [CAL_VPORT_CTRL1\[30:25\] YBLK](#) bit fields. The pixel clock is active at the chosen speed during blanking. VP_HS pulses are provided during vertical blanking. The pixel clock is cut during the idle period.

The timing generator is stalled (VP_PCLK = 0, state-machine stalled) when the current position is in the active video region (waiting for data), but no data is available. VP_PCLK is free running (at the speed defined by [CAL_VPORT_CTRL1\[16:0\] PCLK](#) bit-field) during horizontal and vertical blanking periods. No line PIX_DAT_HS, PIX_DAT_HE, PIX_DAT_VS, PIX_DAT_VE tags are expected by the video port state-machine during blanking periods.

NOTE: Software does not need to configure the size of the image for the video port. This information is extracted from the received datastream. Generally, to generate the vertical blanking, CAL counts the number of active pixels from the last image line.

9.2.3.13 CAL BYS Ports

9.2.3.13.1 CAL BYS Ports Overview

CAL provides one input port (BYS_PI) and one output port (BYS_PO). Video timings and image sizes may be different on the input and output port. It is allowed that:

- Data is sent to BYS_PO and data is received on BYS_PI.
- Data is sent to BYS_PO but nothing is received on BYS_PI.
- Nothing is sent to BYS_PO but data is received on BYS_PI.

9.2.3.13.2 CAL BYS Output Port

The BYS_PO is enabled by setting the [CAL_BYS_CTRL1\[16:0\]](#) PCLK bit field to a value different than 0x0 (the value of 0x0 disables the BYS_PO). The port processes data tagged as PIX_DAT_FS, PIX_DAT_LS, PIX_DAT, PIX_DAT_LE, or PIX_DAT_FE and which belongs to the C-Port ID defined in the [CAL_BYS_CTRL2\[9:5\]](#) CPORTOUT bit field. Other data types are ignored.

A copy of the data sent to the BYS_PO can optionally be sent to the DPCM encoder. This feature is enabled by setting the [CAL_BYS_CTRL2\[10\]](#) DUPLICATEDDATA bit to 0x1. The feature is typically used to produce two versions of the same received input frame:

- One with full resolution that is directly stored in SDRAM or sent to the video port
- Another that has been downscaled and is then sent to SDRAM/video port

NOTE: Data duplication feature uses bandwidth from the CAL internal processing path and must be disabled, if it is not required, by clearing the [CAL_BYS_CTRL2\[10\]](#) DUPLICATEDDATA bit to 0x0. Duplicated data uses the same C-Port ID as the initial data (that is, the [CAL_BYS_CTRL2\[9:5\]](#) CPORTOUT bit field).

The synchronization signals of the BYS_PO (BYS_PO_VS and BYS_PO_HS) are directly controlled by the TAG received together with the data.

The BYS_PO can generate horizontal and vertical blanking in addition to pixels received from the CAL pipeline. The amount of blanking is defined by the [CAL_BYS_CTRL1\[24:17\]](#) XBLK and [CAL_BYS_CTRL1\[30:25\]](#) YBLK bit fields. The pixel clock (BYS_PO_PCLK) is active at the chosen speed during blanking. BYS_PO_HS/HE pulses are provided during vertical blanking. The BYS output port can accept additional data when it generates horizontal or vertical blanking. Therefore, it stalls the processing pipeline, if data for the next line is received during blanking generation. To avoid stalling the internal pipeline, SW must ensure that the horizontal blanking configured for the BYS output port is less or equal than the horizontal blanking provided by the image source.

- The RD DMA does not insert horizontal blanking by default. However, it could be configured to stall the pixel stream at each line end until the BYS out port finishes blanking generation. This feature is enabled by setting the [CAL_RD_DMA_CTRL2\[6\]](#) BYSOUT_LE_WAIT bit. It shall be set when [CAL_BYS_CTRL1.XBLK](#) > 0 and there is concurrent real time traffic to a RD DMA to BYS output traffic through the CAL shared pipeline. Because of the internal delays, the minimum idle time between lines when BYSOUT_LE_WAIT = 1 is 6 functional clock cycles. BYSOUT_LE_WAIT bit shall be cleared when the RD DMA sends data to another destination than the BYS out port. The RD DMA is not stalled during vertical blanking generation. SW must ensure that the BYS out port has completed vertical blanking generation before it sends the next frame. SW shall wait for the IRQ_BYSOUT_VBLANK_END event to occur before starting the next frame.

The pixel clock is cut during the idle period when [CAL_BYS_CTRL2\[11\]](#) FREERUNNING = 0. The pixel clock runs at the speed defined by [CAL_BYS_CTRL1\[16:0\]](#) PCLK during idle when FREERUNNING = 1. The free running pixel clock is not generated before the 1st frame as [CAL_BYS_CTRL1\[16:0\]](#) PCLK and [CAL_BYS_CTRL2\[11\]](#) FREERUNNING register fields. SW could force generation of the pixel clock before the 1st real image frame by sending a dummy frame of 8 pixels x 1 lines to the BYS out port before sending the actual frame.

Similarly to the video port, the `BYS_PO` also generates four `PCLK` pulses before it sends the first pixel. Unlike the video port though, the `BYS_PO` does not try to smooth the pixel rate. Modules attached to the `BYS` out port are expected to be able to receive 0 or 4 pixels per clock cycle and have their own smoothing mechanism.

The pixel clock provided to the `BYS_PO` (`BYS_PO_PCLK`) is controlled by the `CAL_BYS_CTRL1[16:0]` `PCLK` bit field. The same clock generation algorithm is used for the `BYS_PO` as for the video port. For details, see , *Video Port Pixel Clock Generation*. The CAL processing pipeline can be stalled by the `BYS` output port when pixels arrive at a higher rate than what has been configured in the `CAL_BYS_CTRL1[16:0]` `PCLK` bit field.

Typically, the `BYS_PO_PCLK` is set to the maximum speed (that is, `CAL_BYS_CTRL1[16:0]` `PCLK` = 0x10000) but in some cases it may be beneficial to choose a lower value. That is mainly the case when there are large pixel rate variations in the data received and the module attached to `BYS` out cannot keep up with the data rate peaks.

NOTE: Software does not have to configure the size of the image for the `BYS_PO`. This information is extracted from the received datastream. Generally, to generate the vertical blanking, CAL counts the number of active pixels from the last image line.

Some data types can be received by CAL as a complete frame instead of individual lines. Such data will be send as and image of one line on the `BYS` output port.

9.2.3.13.3 *BYS Input Port*

The `BYS` input port (`BYS_PI`) can be enabled by setting the `CAL_BYS_CTRL1[31]` `BYSINEN` bit to 0x1.

The TAGs for the data received on the `BYS_PI` are generated based on the received synchronization signals (`BYS_PI_VS`, `BYS_PI_VE`, `BYS_PI_HS`, and `BYS_PI_HE`). Received data is merged into the CAL internals data pipeline using the C-Port ID defined in the `CAL_BYS_CTRL2[4:0]` `CPORTIN` bit field. Software must ensure that the used C-Port ID is not already used in the pipeline.

The `BYS` input port can generate data tagged as `PIX_DAT_FS`, `PIX_DAT_LS`, `PIX_DAT`, `PIX_DAT_LE` or `PIX_DAT_FE`.

Data from the DPCM decoder (`BYS_PO` data has eventually been filtered out) is merged with data received on the `BYS_PI`. The `BYS_PI` has highest priority as it cannot be stalled. Traffic from the `BYS_PO` may eventually be stalled.

The `BYS_PI` is asynchronous from the functional clock (`CAL_FCLK`). However, its speed is limited to 4 pixels per functional clock cycle.

An `IRQ_BYSIN_OVR` event is triggered when data continues to arrive on the `BYS_PI`, but the video port/write DMA cannot handle it (that is, video port FIFO full/write DMA FIFO full). The `BYS_PI` has a small FIFO that is first filled when back pressure is received. If this FIFO is full as well, it discards data. It tags the next received valid data as `PIX_DAT_FS`, even when the `BYS_PI_VS` signal is not active. That avoids the Write DMA block to send data outside of the allocated buffer space in SDRAM. A `PIX_DAT_FS` resets the address generator to the start of the buffer. But, if a true `PIX_DAT_FS` is lost, the address generator would append data at the end of a full frame and therefore perform writes outside of the allocate SDRAM buffer.

NOTE: The `BYS_PI` does not have a qualifier to indicate the number of valid pixels per active cycle. CAL assumes that each active cycle carries exactly 4 pixels. Practically, that means that the line length is rounded up to the next multiple of 4 by appending dummy data. Software must discard that dummy data (either discard it in the DMA or in the module attached to the video port).

The data stream provided on the `BYS` in port may be corrupted because of an asynchronous SW reset performed in the module connected to `BYS` input port. `LE` / `FE` pulses may be missing in that case. CAL will recover sync on the next received `FS` pulse.

9.2.3.14 CAL Registers Shadowing

Table 9-94 summarizes which CAL registers are shadowed.

Table 9-94. CAL Registers Shadowing

Register	Shadowed	Trigger	Additional Information
CAL_HL_REVISION	No	N/A	
CAL_HL_HWINFO	No	N/A	
CAL_HL_SYSCONFIG	No	N/A	
CAL_HL_IRQ_EOI	No	N/A	
CAL_HL_IRQSTATUS_RAW_j	No	N/A	
CAL_HL_IRQSTATUS_j	No	N/A	
CAL_HL_IRQENABLE_SET_j	No	N/A	
CAL_HL_IRQENABLE_CLR_j	No	N/A	
CAL_PIX_PROC_i[0] EN	Yes	FS @ pixel processing input	Format received on C-Port may change (for example between viewfinder and full frame). However, utilization of separate CPORTs is preferred (if camera sensor permits).
CAL_PIX_PROC_i other bits	No	N/A	Use separate contexts and EN bits, if pixel processing for a given CPORT must be changed on a frame by frame basis
CAL_CTRL	No	N/A	Typically not changed while there is active traffic
CAL_LINE_NUMBER_EVT	No	N/A	
CAL_VPORT_CTRL1	Yes	FS @ video port input	Blanking / PCLK settings may need to be changed on each frame; for example when binning / digital zoom settings change.
CAL_VPORT_CTRL2[] FSRESET bit	No	N/A	Control bit for debug only
CAL_VPORT_CTRL2 other bits	Yes	FS @ video port input	Pixel rate and source CPORT may need to change on the fly (that is, switch between camera modes that use separate CPORTs)
CAL_BYS_CTRL1[31] BYSINEN	Yes	FS @ BYS input port	
CAL_BYS_CTRL1[30:25] YBLK	Yes	FS @ BYS output port	
CAL_BYS_CTRL1[24:17] XBLK	Yes	FS @ BYS output port	
CAL_BYS_CTRL1[16:0] PCLK	Yes	FS @ BYS output port	
CAL_BYS_CTRL2[10] DUPLICATEDATA	Yes	FS @ BYS output port	
CAL_BYS_CTRL2[9:5] CPORTOUT	Yes	FS @ BYS output port	
CAL_BYS_CTRL2[4:0] CPORTIN	Yes	FS @ BYS input port	
CAL_RD_DMA_CTRL	No	N/A	One-shot-operation only
CAL_RD_DMA_PIX_ADDR	No	N/A	One-shot-operation only
CAL_RD_DMA_PIX_OFST	No	N/A	One-shot-operation only
CAL_RD_DMA_XSIZE	No	N/A	One-shot-operation only
CAL_RD_DMA_YSIZE	No	N/A	One-shot-operation only
CAL_RD_DMA_INIT_ADDR	No	N/A	One-shot-operation only
CAL_RD_DMA_INIT_OFST	No	N/A	One-shot-operation only
CAL_WR_DMA_CTRL_k[1:0] MODE	Yes	FS @ CPORT = CAL_WR_DMA_CTRL_k[13:9] CPORT	Resolution may change for a given CPORT. That is not preferred but some sensors may require this mode.
CAL_WR_DMA_CTRL_k other bits	No	N/A	Use separate contexts and MODE bits, if size changes for a given CPORT.
CAL_WR_DMA_ADDR_k	Yes	FS @ CPORT = CAL_WR_DMA_CTRL_k[13:9] CPORT	Output is typically double buffered so that CAL writes one buffer when the other buffer is read.

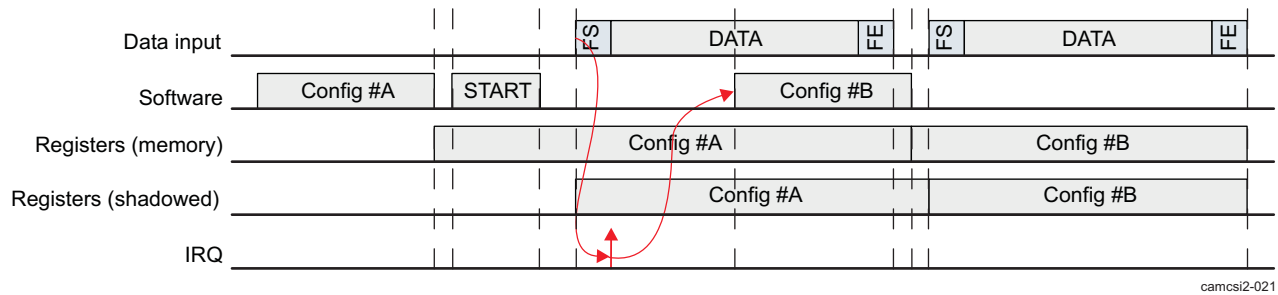

NOTE: Registers that are not shadowed are busy writable. Changes are immediately taken into account and may cause failure, if they are done while the hardware is using the register (that is, outside of the blanking periods).

For all shadowed registers, except `CAL_WR_DMA_ADDR_k`, the content of the shadowed register is copied into the internal copy when the FS of the newly enabled stream is received by the corresponding engine. Said differently, new settings are taken into account just before they are needed. That maximizes time available to the software to change register settings. In particular, the first received FS copies initial settings into a shadow register.

The FS event is detected at the location in the pipeline where the setting applies. Said differently, the copy from shadow to working register does not occur exactly at the same time in all pipeline stages and there is no risk that the shadowing mechanism is activated too late or too early.

Figure 9-26 shows an example. Software writes configuration #A and then starts the processing step. The value from the configuration register is copied into the shadowed register that is used by hardware when the `PIX_DAT_FS` tag is received by relevant pipeline stage. Software may use an IRQ to detect the frame start and provide the settings for the next frame. The frame start interrupt is triggered by the low-level protocol. This happens up to 8 cycles before the `PIX_DAT_FS` tag reaches the processing stage. Therefore, software must ensure that there is a delay of at least 8 functional clock cycles from the `FS_IRQ` to the configuration update. In a real world case, this delay is ensured by the IRQ controller plus software latency. Software must first read the `CAL_HL_IRQSTATUS_j` registers to detect which event has triggered the IRQ before it can update configuration registers.

Figure 9-26. CAL Registers Shadowing Example

camcsi2-021

The `CAL_WR_DMA_ADDR_k` register has a specific shadowing to avoid that multibuffer management is on the critical software path. For more details, see Section 9.2.3.10.4, *Write DMA OCP Address Generation*.

9.2.4 ISS CAL Register Manual

9.2.4.1 CAL Instance Summary

Table 9-95 summarizes the CAL instances.

Table 9-95. CAL Instance Summary

Module Name	L3_MAIN Base Address	Size
CAL_B	0x4221 3000	1 KiB

9.2.4.2 CAL Registers

NOTE: CSI2 (CSI-2) and PPI features and associated registers are not supported in this family of devices.

CSI3 (CSI-3) and OCPI features and associated registers are not supported in this family of devices.

ICM feature and associated registers are not supported in this family of devices.

9.2.4.2.2 CAL Register Description

NOTE: CSI2 (CSI-2), PPI and SCP features and associated registers are not supported in this family of devices.

CSI3 (CSI-3) and OCPI features and associated registers are not supported in this family of devices.

ICM feature and associated registers are not supported in this family of devices.

Table 9-97. CAL_HL_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4221 3000	Instance	CAL_B
Description	IP Revision Identifier (X.Y.R) Used by software to track features, bugs, and compatibility		
Type	R

Table 9-99. CAL_HL_HWINFO

Address Offset	0x0000 0004		
Physical Address	0x4221 3004	Instance	CAL_B
Description	Information about the IP module's hardware configuration, i.e. typically the module's HDL generics (if any). Actual field format and encoding is up to the module's designer to decide.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NPPI_CONTEXTS1		NPPI_CONTEXTS0		NCPORT				VFIFO				WCTX				PCTX				RFIFO				WFIFO							

Bits	Field Name	Description	Type	Reset
31:30	NPPI_CONTEXTS1	Number of contexts for PPI interface #1 Read 0x3: Read 0x2: PPI interface supported with 8 contexts Read 0x1: PPI interface supported with 4 contexts Read 0x0: PPI interface not supported	R	0x2
29:28	NPPI_CONTEXTS0	Number of contexts for PPI interface #0 Read 0x3: Read 0x2: PPI interface supported with 8 contexts Read 0x1: PPI interface supported with 4 contexts Read 0x0: PPI interface not supported	R	0x2

Bits	Field Name	Description	Type	Reset
27:23	NCPORT	Number of supported CPORTs (including CPORT #0) minus 1. That number typically corresponds to the number of CPORTs that can provide data from OCPI. E.g. NCPORT=7 means that CAL implements 8 CPorts but one of them (CPORT0) is typically used for data read from memory and typically 7 (CPORT1~CPORT7) can be used for data received on OCPI Note: Equals NCPORT generic parameter minus 1	R	0x07
22:19	VFIFO	Video port FIFO size	R	0x9
18:13	WCTX	Number of implemented DMA write contexts	R	0x08
12:8	PCTX	Number of implemented pixel processing contexts	R	0x04
7:4	RFIFO	Read FIFO size 2 ^{RFIFO} words of 16 bytes	R	0x6
3:0	WFIFO	Write FIFO size 2 ^{WFIFO} words of 16 bytes	R	0x9

Table 9-115. CAL_CTRL

Address Offset	0x0000 0100	Instance	CAL_B
Physical Address	0x4221 3100		
Description	Global control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MFLAGH								RESERVED	RD_DMA_STALL	PWRSCPCLK	MFLAGL					LL_FORCE_STATE					BURSTSIZE	TAGCNT			POSTED_WRITES						

Bits	Field Name	Description	Type	Reset
31:24	MFLAGH	Refer to section CAL Write DMA Real Time Traffic.	RW	0xFF
23	RESERVED		R	0
22	RD_DMA_STALL	Controls if the pixel stream from the RD DMA's FIFO to the internal pipeline shall be stalled when MFlag/=0. Shall be enabled to protect real time traffic against non real time, memory to memory dataflows through CAL. 0x0: Disabled. 0x1: Enabled. The MFlag information is propagated to the RD DMA FIFO readout control.	RW	0
21	PWRSCPCLK	Controls autogating of the PWRSCP clock 0x0: PWRSCP clock is automatically cut when it isn't needed. 0x1: PWRSCP clock is free running	RW	0
20:13	MFLAGL	Refer to section CAL Write DMA Real Time Traffic.	RW	0xFF
12:7	LL_FORCE_STATE	Forces the state of the CSI-3 low level protocol state machine. Intended to recover synchronization Writing 0 into this register has no effect. Reads always return 0s bit0: 0: the next OCPI transaction for this CPORT will only contain data 1: the next OCPI transaction for this CPORT will contain the CSI-3 packet header bit1~5: CPort ID (1..31)	W	0x00
6:5	BURSTSIZE	Maximum allowed burst size for the write DMA. 0x0: 16 bytes 0x1: 32 bytes 0x3: 128 bytes 0x2: 64 bytes	RW	0x3
4:1	TAGCNT	Maximum number of outstanding OCP transactions = TAGCNT+1	RW	0xF
0	POSTED_WRITES	0x0: Generate only non posted writes 0x1: Generate only posted writes	RW	0

Table 9-129. CAL_RD_DMA_CTRL

Address Offset	0x0000 0140	Instance	CAL_B
Physical Address	0x4221 3140		
Description	Read DMA control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCLK																OCP_TAG_CNT		BW_LIMITER				INIT		GO							

Bits	Field Name	Description	Type	Reset
31:15	PCLK	Controls the data rate at which data is read from the read DMA FIFO and sent to the internal processing pipeline. Data rate = FCLK * 8 * PCLK / 2 ¹⁶ Bytes/s HW guarantees that data is never sent at faster rate than defined by this register. The data may be sent at slower rate when the RD DMA FIFO is empty or the processing pipeline is busy (data from OCPI has higher priority) Missed slots are not cummulated. Valid range: 0 .. 2 ¹⁶	RW	0x0 0000
14:11	OCP_TAG_CNT	Maximum allowed number of outstanding OCP read requests minus 1 (i.e. 0xF meand up to 16 outstanding requests)	RW	0x0
10:2	BW_LIMITER	Defines a minimum cycle count between to consecutive read requests issued by the RD DMA. Used to limit the SDRAM load in memory to memory mode. The pixel rate should be controlled at video port level when data read from memory is send to the video port. Valid range = 9..4095 cycles	RW	0x000
1	INIT	Enable reading of DPCM decoder initialization data from SDRAM 0x0: Disabled 0x1: Enabled	RW	0
0	GO	Start data read from memory. This bit is set by SW and automatically cleared by HW when the frame has been processed. Write 0x0: No effect Write 0x1: Start read DMA Read 0x1: Read DMA BUSY / it is currently fetching data from memory and sends it to the processing pipeline Read 0x0: Read DMA idle / ready to receive the next start trigger from SW	RW	0

9.3 ISS Image Signal Processor (ISP)

This section describes the Image Signal Processor (ISP).

9.3.1 ISS ISP Overview

The image signal processor (ISP) is part of the image subsystem (ISS) of the device and is a key component for imaging and video applications. ISP is comprised of the following sub-modules: video port (VP), image pipe interface (IPIPEIF), image pipe module (IPIPE), resizer (RSZ), hardware auto exposure, auto white balance, and auto focus engine (H3A), image sensor interface accelerator (ISIF), Global Local Brightness Contrast Enhancement (GLBCE), Noise Filter 3V (NSF3V), Chroma Noise Filter (CNF), and buffer logic (BL). For better understanding, see first the top-level ISS diagram and feature list in [Section 9.1, ISS Overview](#).

9.3.1.1 ISS ISP Features

The video-processing hardware removes the need for expensive camera modules to perform processing functions. The ISS can support the following features:

- Memory-to-memory processing
- Up to 532 MHz pixel throughput
- Statistic data collection:
 - Memory-to-memory operation
 - Data collection for auto exposure
 - Data collection for auto white balance
 - Data collection for auto focus
 - Boundary signal calculation for video stabilization
- High-ISO Video Noise Filtering (NSF3V)
 - Up to 532 MPix/s
 - Bayer RGB, YUV422, and YUV420 formats
 - 12-bit datapath bit width
 - 2816 pixels input line memory size
 - Throughput of 1 data points per cycle, without the overhead
 - For Bayer, 1 pixel = 1 data point
 - For YUV422, 1 pixel = 2 data points
 - For YUV420, 1 pixel = 1.5 data points
 - Adaptive noise level threshold
 - Inter-color-luma-estimation affecting noise threshold
 - Soft thresholding
 - Edge enhancement
 - Radial shading gain
 - Desaturation for YUV
 - Use luma to drive chroma noise threshold in YUV422
 - Support output width = input width by replicating border pixels, requires at most 48 extra pixel of processing time per row
 - Separately replicate-or-trim support for left and right borders
 - Support output height = input height by replicating top/bottom border pixels, requires 7 extra rows of processing time
 - Interleaved processing options
 - Image framing
 - Single frame and video support, flexible interrupt configuration

- Global and Local Brightness Contrast Enhancement (GLBCE)
 - Up to 532 MPix/s
 - 2816 pixels line memory size
 - Bayer image: 16-bit input, 12-bit output
 - Backward compatibility with previous devices and ISP functionality when GLBCE is disabled
- IPIPE front end: RAW data processing:
 - Memory-to-memory processing
 - 16-bit-wide RAW Bayer data path between image and sensor linearization module
 - 12-bit-wide RAW Bayer data path between sensor linearization module and gamma correction module. Gamma correction module outputs 10-bit data.
 - Programmable Bayer RGB positions
 - Sensor data linearization for dynamic range extension
 - Programmable 2D lens shading compensation (LSC) correction
 - Per-pixel gain and offset control
 - Black level compensation
 - Boxcar filter
 - Data collection for histogram generation
 - Defect pixel correction (LUT_DPC) with look-up table (LUT)
 - Defect pixel correction (OTF_DPC) with on-the-fly detection and correction
 - 2D noise filtering
 - Green imbalance correction (GIC)
 - Digital gains and offset
 - 8- to 10-bit A-law decompression and 10- to 8-bit A-law compression
- IPIPE back end: RGB and YUV data processing:
 - RGB-to-RGB color correction
 - Gamma correction (GC)
 - RGB to YUV4:2:2: Color conversion, cosited Chroma filtering and downsampling
 - 2D edge enhancement (EE)
 - 3D LUT for color correction
 - False Chroma suppression (FCS)
- Two resizers (RSZ):
 - Performance: input and output rates up to 532 MPix/s
 - YUV4:2:2 to RGB56, ARGB888, YUV4:2:2, and YUV4:2:0 data output
 - YUV4:2:0 to YUV4:2:0 data output
 - RAW to RAW data output
 - Range from x1/4096 to x20. Supports memory-to-memory rescaling.
- Chroma Noise Filter (CNF)
 - Removes residual chroma noise by filtering UV data component of the image with noise filter
 - 2816 pixels line memory size
 - Support 8-bit UV input (UV part of YUV420) One pixel per cycle and output UV format
 - CDS (Chroma Down Sampling) and CUS (Chroma Up Sampling)
 - CNF available for RSZ1 only

The ISP comprises the following modules:

- IPIPE interface (IPIPEIF)
- Image sensor interface (ISIF) accelerator

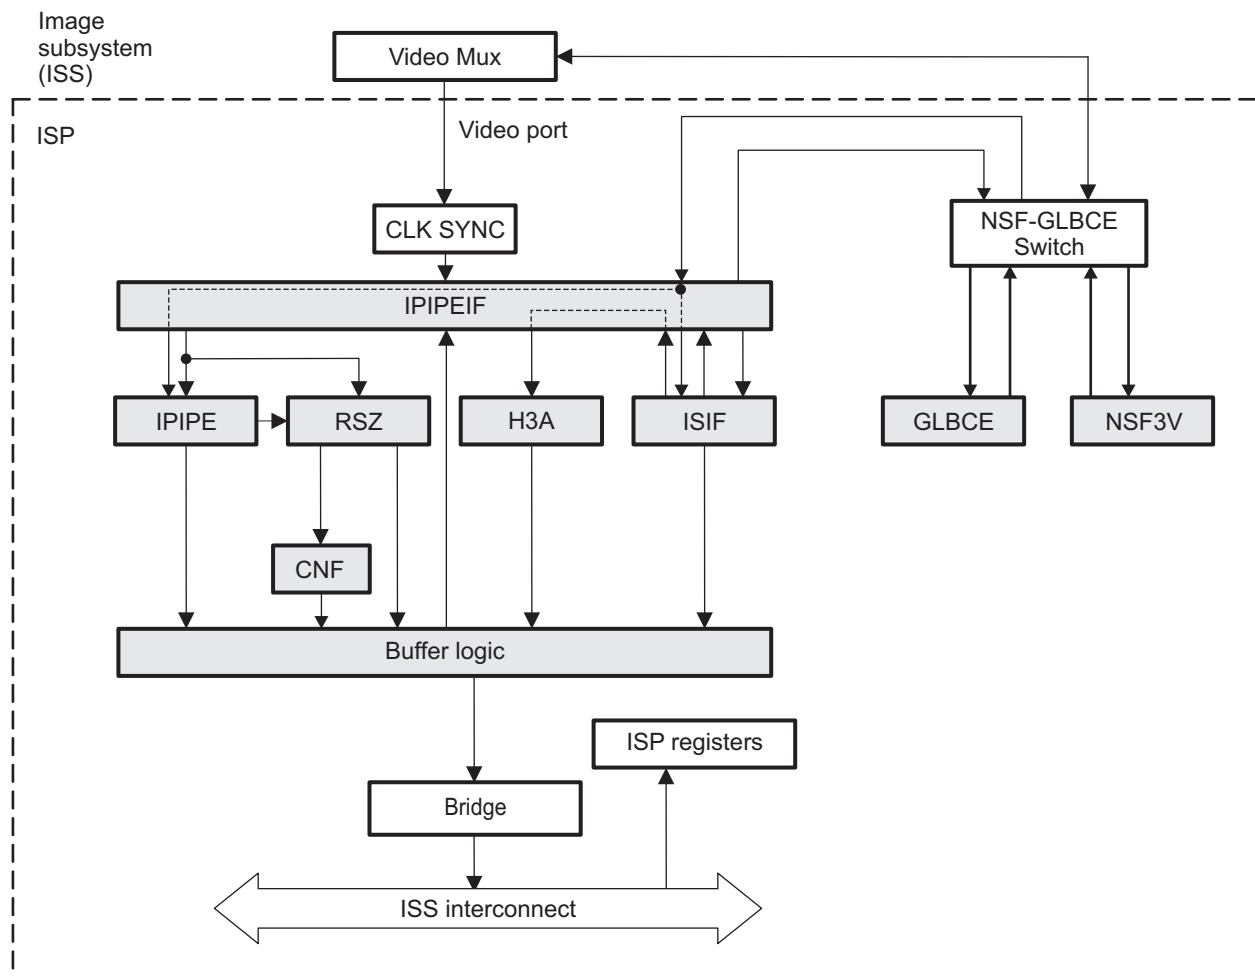

- Auto exposure, auto white balance, and auto focus engine (H3A)
- Image pipe accelerator (IPIPE)
- Two resizer (RSZ) accelerators
- Buffer logic (BL): Receives module requests, performs arbitration, and creates read/write bursts to the memory subsystem

9.3.1.2 ISS ISP Block Diagram

Figure 9-27 is the ISP top-level block diagram.

The ISP 128-bit master port and 32-bit slave port are connected to the level 3 interconnect (L3_MAIN).

Figure 9-27. ISS ISP Block Diagram

camisp-003

9.3.2 ISS ISP Integration

This section describes the integration of the ISP modules in the ISS and includes information about clocks, resets, and hardware requests.

The ISP is part of the ISS of the device and is a key component for imaging and video applications such as camera viewfinder, video record, and still image capture.

9.3.2.1 ISS ISP PRCM Interface

The ISP and its internal modules, as integrated in the ISS, use the same power and clock management details. See [Section 9.1.2, ISS Functional Description](#), for the ISP top-level power, reset, and clock management (PRCM) interface.

9.3.2.1.1 ISS ISP Clocks

The PRCM module, through the local power and clock management inside the ISS, provides a unique PCLK that can be enabled from the [ISP5_CTRL](#) register.

The modules inside the ISP require three clocks:

- PCLK: This clock is asynchronous to the other clocks. It is provided by the module sending the data to the IPIPEIF module on the VP. The frequency is up to 532 MHz.
- ISP_FCLK: This clock is sourced from ISS_MAIN_FCLK and is synchronous with the configuration clock domain. This is the clock used for the MTC interface. The frequency is up to 532 MHz.
- GCK_MMR: This is the clock for the configuration bus. It is created from the ISP_FCLK and runs at half the speed of the ISP_FCLK. The frequency is up to 266 MHz.

9.3.2.1.2 ISS ISP Reset

The ISP supports global software reset along with internal hardware reset, if needed.

Software reset is done through the [ISP5_SYSCONFIG\[1\]](#) SOFTRESET bit. Before issuing a software reset, the ISP must be in standby mode. The following must be done:

1. Ensure that the interfaces are stopped from sending data and/or the ISP modules are disabled. Before reset, the last interrupt triggered by the ISP when the frame processing completes is RSZ_INT_DMA. RSZ_INT_DMA must be used to enable clean termination of the processing. Software must wait a few hundred cycles to trigger a soft reset after RSZ_INT_DMA is asserted; this is to ensure that the BL is completely drained.
2. Ensure that [ISP5_SYSCONFIG\[5:4\]](#) STANDBYMODE = 2 (smart standby). Set the [ISP5_CTRL\[24\]](#) MSTANDBY bit to 1 and poll for [ISP5_CTRL\[20\]](#) MSTANDBY_WAIT = 1. Then, the soft reset can be applied ([ISP5_SYSCONFIG\[1\]](#) SOFTRESET = 1).

In case an ISP overflow event happens (for example, RSZ_FIFO_OVF, ISIF_OVF, etc.), it is not sufficient to reset the ISP. In that case a reset must occur at the ISS level. ISP underflow events do not require any special attention since these are internally managed by ISS stalling mechanism

9.3.2.2 ISS ISP Interrupt Tree

There are four ISP output interrupt lines that are mapped to the ISS top interrupt request (IRQ) merger (for more information, see [Section 9.1.2.1.1, ISS Interrupt Merger](#)). [Table 9-201](#) summarizes the ISP submodule interrupt events that can be mapped to the four ISP interrupt lines. An interrupt event can be enabled on any of the four interrupt lines through the [ISP5_IRQENABLE_SET_i](#) and [ISP5_IRQENABLE_SET2_i](#) registers (i = 0 to 3, one register per interrupt line). Each event must be enabled on only one interrupt line.

Table 9-201. ISS ISP Interrupt Tree Table

Register	Module	Destination	Comments
ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ	IPIPEIF	ISP to ISS merger four IRQ lines	See Section 9.3.2.3.1 .

ISP5_IRQENABLE_SET_i[0] ISIF_INT_0						

9.3.2.3 ISS ISP IPIPEIF Integration

9.3.2.3.1 ISS ISP IPIPEIF Interrupts

The IPIPEIF module generates two interrupts:

- IPIPEIF_IRQ: This event is triggered to the BL module when a new frame starts (VS signal). The interrupt is active high and is asserted for one GCK_MMR clock cycle.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ bit (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 9.1.2, ISS Functional Description](#).

For additional information on IPIPEIF events see [Section 9.3.3.4.16, ISS ISP IPIPEIF Module Events and Status Checking](#).

9.3.2.4 ISS ISP IPIPE Integration

9.3.2.4.1 ISS ISP IPIPE Interrupts

IPIPE can generate several interrupts:

- IPIPE_INT_DPC_RNEW0 and IPIPE_INT_DPC_RNEW1: This event is triggered when there is permission to initialize LUT-DPC table lines 0 and 1.

- IPIPE_INT_DPC_INI: This event is triggered when the defect pixel correction (DPC) table is initialized.
- IPIPE_INT_HST: This event is triggered when the histogram is done.
- IPIPE_INT_BSC: This event is triggered when boundary signal calculation is done.
- IPIPE_INT_DMA: This event is triggered when the boxcar SDRAM transfer is done. On this timing, IPIPE_INT_EOF is sent to the BL. This event is active high for one GCK_MMR clock cycle.
- IPIPE_INT_LAST_PIX: This event is triggered when the last pixel of a frame comes into IPIPE. This event is active high for one GCK_MMR clock cycle. Also, this signal can not be used if DPC is used before NSF3V.
- IPIPE_INT_EOF: This event is triggered for end of frame.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i register (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 9.1.2, ISS Functional Description](#).

9.3.2.5 ISS ISP RSZ Integration

9.3.2.5.1 ISS ISP RSZ PRCM Interface

9.3.2.5.1.1 ISS ISP RSZ Reset

The RSZ module has no stand-alone software reset. RSZ must be reset at the ISP level. See [Section 9.3.2.1.2, ISS ISP Reset](#).

9.3.2.5.2 ISS ISP RSZ Interrupts

RSZ can generate several interrupts:

- RSZ_INT_EOF0: This event is triggered for end of frame.
- RSZ_INT_EOF1: This event is triggered for end of frame.
- RSZ_FIFO_IN_BLK_ERR: This event is triggered when the minimum vertical blanking period has not been respected, thus causing errors in the input data buffering submodule. This event is triggered when the RSZ_INT_REG event of frame N is triggered before RSZ_INT_DMA of frame N + 1. This event typically occurs at the transition between two frames because there is not enough vertical blanking between frames. Hardware cannot recover from this error. It requires a reset. It is a requirement that despite the error the RSZ module must finish correctly: ongoing requests are completed and further requests are blocked.
- RSZ_FIFO_OVF: This event typically occurs while processing a frame, because the VP pixel clock is too high. Because hardware cannot recover from this error, a reset is required. It is a requirement that despite the error the RSZ module must finish correctly: ongoing requests are completed and further requests are blocked.

This event signifies overflow in two different scenarios:

- In Bypass or Operating (normal/downscale) modes, the RSZ_FIFO_OVF event is triggered when an overflow occurs in the input circular data buffer. The `rsz_stall_input` signal can be asserted by programming appropriate thresholds to prevent input FIFO overflow.
- In Pass-through mode, the RSZ_FIFO_OVF event is triggered when an overflow occurs in the output MTC buffer. There is no hardware mechanism to prevent overflow in Pass-through mode.
- RSZ_INT_CYC_RZA/RSZ_INT_CYC_RZB: This event is triggered as circular interrupt every time that [RSZ_IRQ_RZA/RSZ_IRQ_RZB](#) output lines are written to the RZA_SDR_Y/RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value must be such that the circular buffer vertical size is a multiple of [RSZ_IRQ_RZA/RSZ_IRQ_RZA](#).
- RSZ_INT_DMA: This event is triggered when the last EOF (of the two MTC interfaces) is sent to the BL and the RSZ core returns to idle. This event is active high for one GCK_MMR clock cycle.
- RSZ_INT_LAST_PIX: This event is triggered when the last pixel of the valid area is received. This event is active high for one GCK_MMR clock cycle.
- RSZ_INT_REG: This event is triggered when the new value of the shadowed registers, if updated,

takes effect on the next RSZ_INT_REG event. Then again, shadowed registers can be updated for the next frame after the RSZ_INT_REG event is triggered. This event is active high for one GCK_MMR clock cycle.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i register (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 9.1.2, ISS Functional Description](#).

9.3.2.6 ISS ISP H3A Integration

9.3.2.6.1 ISS ISP H3A Interrupts

H3A can generate the following interrupts:

- H3A_INT: This event is triggered at the end of the last window or last paxel, whichever completes last. This always triggers at the same time as H3A_INT_EOF.
- H3A_INT_EOF: This event is triggered and generated at the end of the last window. This event is active high for one GCK_MMR clock cycle.

The interrupts are enabled from ISP5_IRQENABLE_SET_i register (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 9.1.2, ISS Functional Description](#).

9.3.2.7 ISS ISP ISIF Integration

9.3.2.7.1 ISS ISP ISIF Interrupts

The ISIF can generate several interrupts:

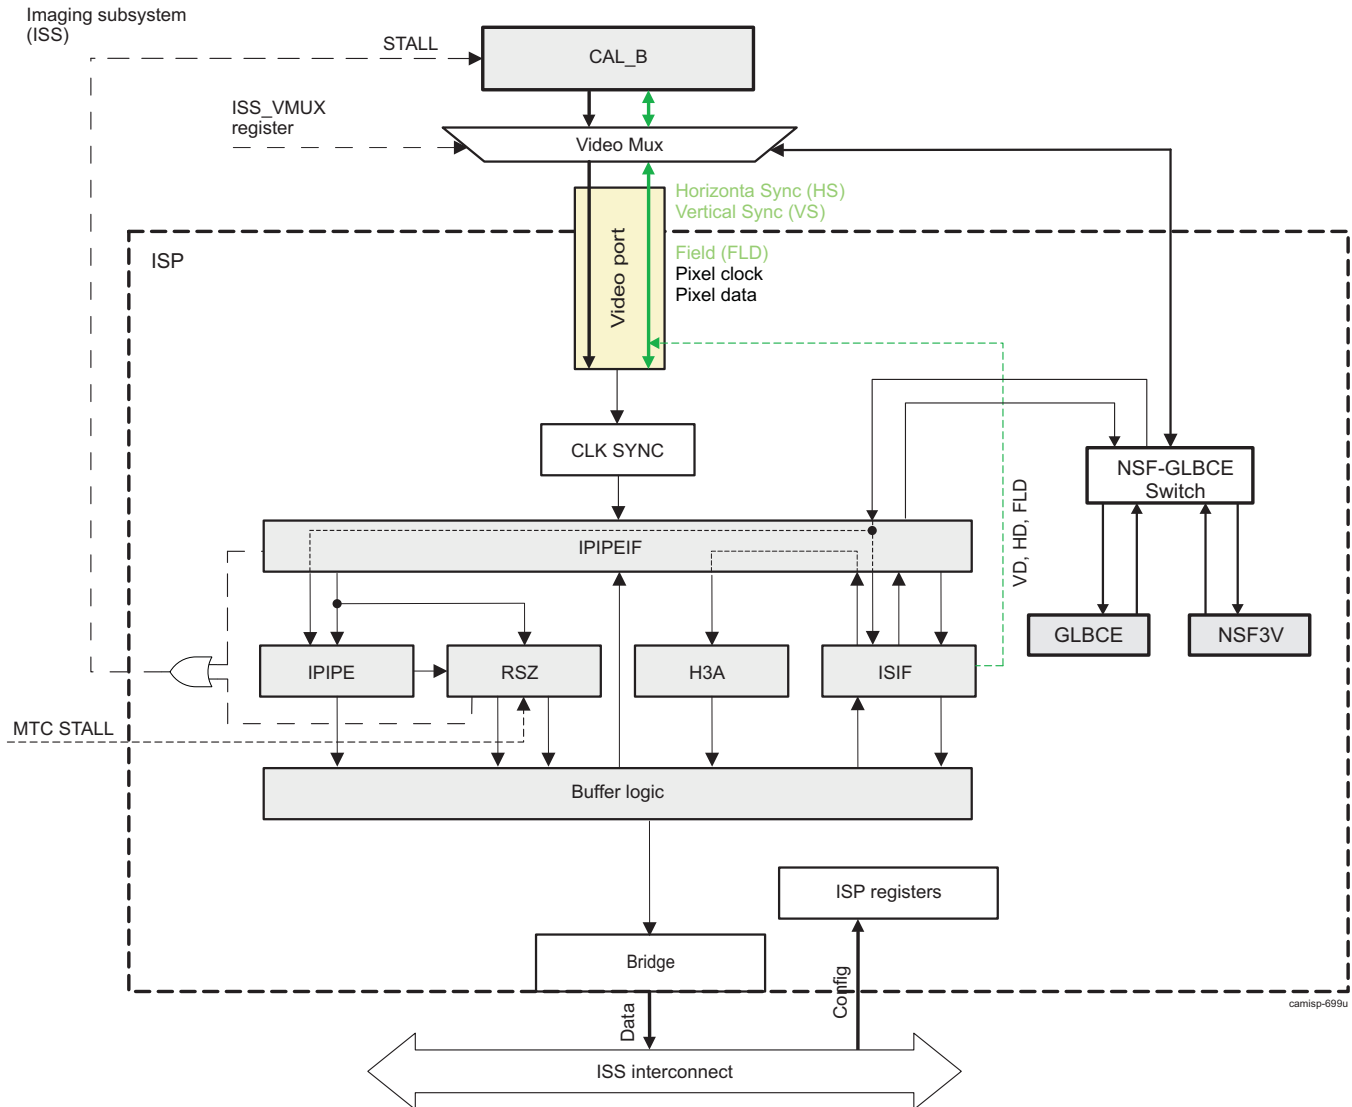

- ISIF_INT_0: This event is triggered when the VD0 interrupt on line 0 is configured. The VD0 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT0. For more information, see [Section 9.3.3.9.20.1](#).
- ISIF_INT_1: This event is triggered when the VD1 interrupt on line 1 is configured. The VD1 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT1. For more information, see [Section 9.3.3.9.20.1](#).
- ISIF_INT_2: This event is triggered when the VD2 interrupt on line 2 is configured. The VD2 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT2. SFor more information, see [Section 9.3.3.9.20.1](#).
- ISIF_INT_3: This event is triggered LSC interrupt is an interrupt issued by the 2D-LSC block. For more information, see [Section 9.3.3.9.10.1.5](#).

The interrupts are enabled from the ISP5_IRQENABLE_SET_i register (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from ISP is sent to the ISS top level where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 9.1.2, ISS Functional Description](#).

9.3.2.8 ISS ISP BL Integration

See [Section 9.3.2, ISS ISP Integration](#).

Figure 9-29. ISS ISP VP High-Level Diagram

9.3.3.1.2 ISS ISP VP Data Formats

The VP can be used to connect external modules to the ISP. Data paths inside the ISP hardware depend on the image format (RAW RGB, YUV4:2:2, JPEG, etc.). Table 9-202 shows how the CAL_B module is connected to the VP in function of the image format with corresponding ISIF_CGAMMAWD[4:1] GWDI register bit-field settings.

Table 9-202. ISS ISP VP Format Mapping

9.3.3.1.3 ISS ISP VP Top-Level Communication With CAL_B

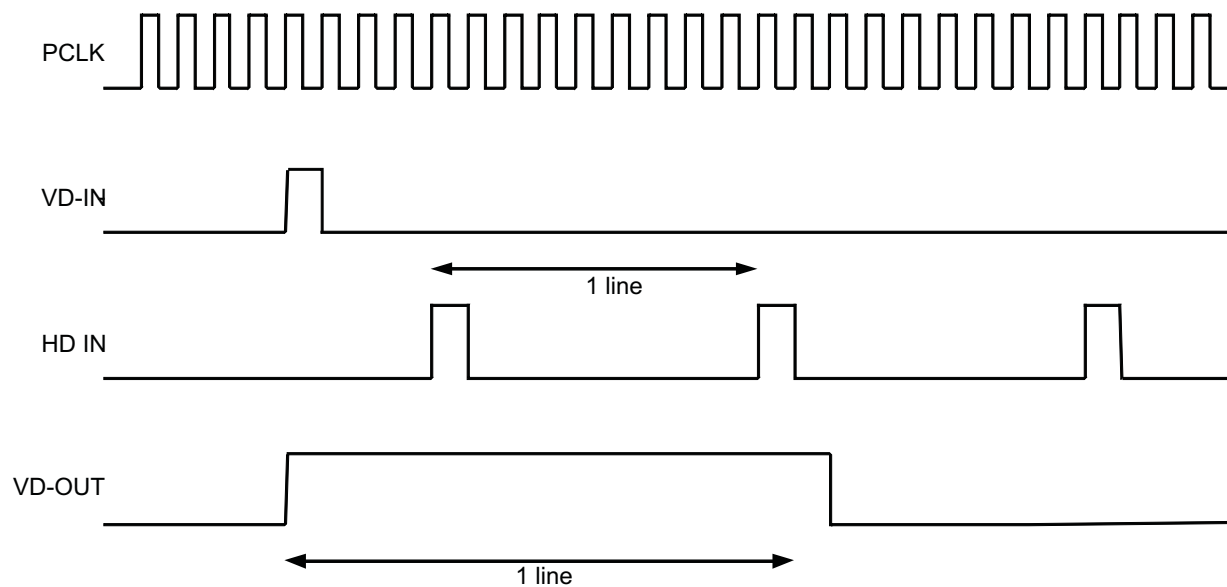

At the ISS level, the VP is connected to the VP of the CAL_B interface module. The selection, which interface VP is connected to the ISP is done on ISS top level through ISS_VMUX register bit fields.

VP implementation differences force the introduction of a bridge between the CAL_B and the ISP VP. The role of the bridge is to perform VD pulse extension. The CAL_B module assumes that the VD signal is active for at least one pixel clock cycle, and the CAL_B module assumes that the VD signal is asserted for four pixel clock cycles. However, the ISP assumes that the VD pulse is active on at least one line.

Figure 9-30 shows how the VD pulse extension works. Assume that VD-IN is the VD signal at the input of the pulse extension bridge, and VD-OUT is the VD signal at the output of the pulse extension bridge.

VD-OUT is asserted at the same time as VD-IN. VD-OUT is kept high until one full line is received. A line is delimited by two rising edges of the HD signal. VD-OUT is deasserted on the next cycle after the falling edge of the HD signal.

Figure 9-30. ISS ISP VP VD Pulse

camss-691

The `ISP5_CTRL[23] VD_PULSE_EXT` bit controls whether the VD extension bridge is enabled or disabled. By default, the bridge is enabled. When the bridge is disabled, the VD pulse must be unmodified: `VD-OUT = VD-IN`. At the ISS level, it is expected that `ISP5_CTRL[23] VD_PULSE_EXT = 1` when the VP gets data from the CAL_B module.

CAUTION

A minimum of four lines per frame is required on the VP when the VD pulse extension bridge is enabled; therefore, the VD extension bridge is not functional if a 1-/2-/3-line frame is sent to the VP.

9.3.3.1.4 ISS ISP VP Pixel Clock Inversion

The ISP always uses the rising edge of the pixel clock to sample the pixel data. The ISP provides the capability to invert the pixel clock so it can shift the resampling of a pixel clock period by half. This is controlled by the `ISP5_CTRL[22] PCLK_INV` bit. By default, the inversion is disabled. The pixel clock must be disabled at ISS level before setting the `PCLK_INV` bit to 0x1. This can be done through the proper `ISS_CLKCTRL[] <module>_PCLK` register bit on ISS top level, depending on the interface that is sending data on the ISP video port.

The 4 bits in [Table 9-203](#) are resynchronized from the GCK_MMR clock domain to the PCLK clock domain. There must be at least three clock cycles between the time these bits are modified and the HD/VD pulse for start of frame comes.

Table 9-203. ISS ISP VP GCK_MMR to PCLK Clock Resynchronization

Module	Register	Bit Field
ISP	ISP5_CTRL	VD_PULSE_EXT
ISIF	ISIF_MODESET	HDVDD
ISIF	ISIF_MODESET	FIDD
ISP	ISP5_CTRL	ISIF_CLK_ENABLE

9.3.3.2 ISS ISP GLBCE Functional Description

9.3.3.2.1 ISS ISP GLBCE Overview

The Global Local Brightness Contrast Enhancement module performs dynamic range compression or tone mapping of an input image based on a model of the human visual system. It is used in a ISP to produce most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations. The module supports:

- Up to 532 MHz operation; up to 532 MPix/s processing (one pixel/cycle)
- Up to 2816 pixel/line
- Bayer image
- 12bit to 16 bit Input, 16 bit output
- Companded data (12-bit/14-bit to 20bit) is supported
- When GLBCE is off, ISP is backward compatible with previous devices

[Figure 9-31](#) show the GLBCE module connections to other submodules of the ISP.

Iridix generates effective tone curves by analyzing the regions surrounding each pixel. The tone curves generated by iridix are based on an asymmetry curve which is then shaped and controlled by a number of parameters that control the gain limitation weighting towards shadows, mid tones and highlights.

9.3.3.2.3.1 ISS ISP GLBCE Core Key Parameters

Table 9-204 shows the key parameters within the iridix core. It is recommended that all parameters be set statically to their recommended values other than the iridix strength parameter, which should be controlled dynamically with scene content. The calculation of iridix strength is explained in Section 9.3.3.2.3.2.

Table 9-204. ISS ISP GLBCE Core Key Parameters

Parameter	Description
iridix strength	This register sets iridix processing strength.
	0x00: Video data will not be processed at all, and will pass to the output unchanged.
	0xFF: Maximum processing strength.
Variance space	This register affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). If this parameter is set to zero, the sensitivity to small areas is maximized (i.e. the transform becomes more local). When this parameter is set to 0xF, the transform deemphasizes small local details, and the transform becomes more global
Variance intensity	For a high-contrast image with shadows and highlights, a small value will cause iridix to adjust shadows and highlights almost independently. A large variance causes iridix to become progressively more global, meaning that the presence of highlights affects the processing of shadows and vice-versa.
Slope min limit	This register is used to restrict the slope of the tone curve generated by iridix. When this parameter is set to 0x00, the tone curve slope generated by iridix is not limited.
	When this value is set to 0xFF, iridix will not generate a tone curve with a slope less than 3/4. Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-128
Slope max limit	This register is used to restrict the slope of the tone-curve generated by iridix. When this parameter is set to 0xFF, the tone curve slope generated by iridix is not limited.
	When this value is set to 0x00, iridix will not generate a tone-curve with slope greater than 16/15 (48°). Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-160. For noisy images, lower values should be used.
Black level	The value stored in this register will be used as the zero level for iridix processing in all data channels. Data below this value will not be processed and remain unchanged.
White level	The value stored in this register will be used as the white level for iridix processing in all data channels. Data above this value will not be processed and remain unchanged.
Asymmetry LUT	This look-up-table is 33 words, each of which is 16-bits. The asymmetry function is used to balance the iridix effect between the dark and bright regions of the image.
Forward perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is presented to the core, this look-up-table must be used to map the linear data to the perceptual space so that iridix can perform its perceptual functions.
Reverse perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is required from the output of the core, this look-up-table must be used to map the data from the perceptual space back to linear space for further processing in the pipeline.

9.3.3.2.3.2 ISS ISP GLBCE Iridix Strength Calculation

This section describes how the dynamic parameter, iridix strength, is calculated.

NOTE: Dynamic range of a digital camera can be described as the ratio of maximum light intensity measurable (at pixel saturation), to minimum light intensity measurable (but above read-out noise). This is a very important concept to consider when computing iridix strength, because the gain applied by iridix is also proportional to the visible boost of noise in the image. The maximum gain applied by iridix should be determined by the dynamic range of the camera system. This is governed by the equation presented in this section.

With iridix strength is zero, all tone curves are linear for all images. As iridix strength is increased, the variation between curves in shadows, mid tones and highlights increases, resulting in increasing compression of global dynamic range.

Iridix strength is calculated as follows:

Figure 9-32. ISS ISP GLBCE Iridix strength formula

$$\text{irridix strength} = \text{Max}\left(0, \text{Min}\left(\frac{\text{IR_Gain_Target} - 1}{\text{IR_Gain_Max} - 1}, f(\text{analog gain})\right)\right) * 255$$

camisp-843

Where:

- IR_Gain_Target is the desired iridix gain to be applied to the image. This is calculated from the image's histogram on a per-frame basis by the ISP's auto exposure algorithm. The histogram is analysed to compute an exposure ratio for the desired global histogram shift. This computed exposure ratio is then used to feed a look-up-table which in turn generates the IR_Gain_Target parameter.
- IR_GainMax is the maximum iridix gain. If the fwd_percep_lut is disabled, then the IR_GainMax should be set to 64, and if the fwd_percep_lut is enabled, then the IR_Gainmax should be set to 16.
- f(analog gain) is a function that determines the maximum iridix strength in relation to noise. f(analog gain) is characterised as follows:

Figure 9-33. ISS ISP GLBCE Iridix f(analog gain) function

camisp-844

f(analog gain) should only be used when the ISP is in linear mode. Otherwise, it should be set to 1

9.3.3.2.3.3 ISS ISP GLBCE Iridix Configuration Registers

9.3.3.2.3.3.1 ISS ISP GLBCE Iridix Frame Width

Frame Width is the number of pixels in an active line and is controlled from [GLBCE_FRAME_WIDTH\[15:0\]](#) VAL. Recommended value 2560 (decimal)

9.3.3.2.3.3.2 ISS ISP GLBCE Iridix Frame Height

Frame Width is the number of pixels in an active line and is controlled from [GLBCE_FRAME_HEIGHT\[15:0\]](#) VAL. Recommended value 1920 (decimal)

9.3.3.2.3.3.3 ISS ISP GLBCE Iridix Control

This is the main control register for the iridix core is [GLBCE_CONTROL0](#) where GLBCE is enabled/disabled and the type of processing algorithm is selected.

9.3.3.2.3.3.4 ISS ISP GLBCE Iridix Control

This is the main control register for the iridix core is [GLBCE_CONTROL0](#) where GLBCE is enabled/disabled and the type of processing algorithm is selected. Recommended value 6 (decimal)

9.3.3.2.3.3.5 ISS ISP GLBCE Iridix Strength

[GLBCE_STRENGTH_IR](#)[7:0] VAL register sets the processing strength of the iridix core. Recommended value 128 (decimal)

9.3.3.2.3.3.6 ISS ISP GLBCE Iridix Variance

The [GLBCE_VARIANCE](#) parameter affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). [GLBCE_VARIANCE](#)[7:4] VARIANCEINTENSITY recommended value 12 (decimal). [GLBCE_VARIANCE](#)[3:0] VARIANCESPACE recommended value 7 (decimal).

9.3.3.2.3.3.7 ISS ISP GLBCE Iridix Dither

When the number of color gradations of a display device is small (for example 6 bits per color), pixel dithering can make gradients look smother. Dithering of the least significant bits is applied and then these bits can be later truncated. The three least significant bits (D2, D1, D0) of this [GLBCE_DITHER](#) register are responsible for the strength of dithering. There are 4 possible levels of dithering. Recommended value 0 (decimal)

9.3.3.2.3.3.8 ISS ISP GLBCE Iridix Amplification Limit

The parameters dark amplification limit and bright amplification limit are used to restrict the luminance space in which iridix can adaptively generate tone curves for each pixel. [GLBCE_LIMIT_AMPL](#)[7:4] BRIGHTAMPLIFICATIONLIMIT recommended value 0 (decimal). [GLBCE_LIMIT_AMPL](#)[3:0] DARKAMPLIFICATIONLIMIT recommended value 0 (decimal).

9.3.3.2.3.3.9 ISS ISP GLBCE Iridix Slope Min and Max

[GLBCE_SLOPE_MIN](#)[7:0] SLOPEMINLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 64 (decimal).

[GLBCE_SLOPE_MAX](#)[7:0] SLOPEMAXLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 72 (decimal).

9.3.3.2.3.3.10 ISS ISP GLBCE Iridix Black Level

The value stored in the Black Level register [GLBCE_BLACK_LEVEL](#)[15:0] VAL will be used as the zero level for iridix processing in all data channels. Data below the Black level will not be processed and remain unchanged. Recommended value 0 (decimal).

9.3.3.2.3.3.11 ISS ISP GLBCE Iridix White Level

The value stored in White Level register [GLBCE_WHITE_LEVEL](#)[15:0] VAL will be used as white level for iridix processing in all data channels. Data above White level will not be processed and stay unchanged. Recommended value 65535 (decimal).

9.3.3.2.3.3.12 ISS ISP GLBCE Iridix Asymmetry Function Look-up-table

The Asymmetry function is used to balance the iridix effect between the dark and bright regions of the image. The Asymmetry Function Lookup Table geometry is 33 words, each of which is 16-bits wide. [GLBCE_LUT_FI_00](#)

[GLBCE_LUT_FI_01](#)

... repeat until...

[GLBCE_LUT_FI_32](#)

Recommended values (decimal):

0:5377:10218:14600:18585:22224:25561:28631:31466:34092:36530:38801:40921:42904

 :61429:62322:63176:63995:64781:65535

The C-code for generating the Asymmetry LUT is shown below:

```
#include <math.h>

int AsymmetryTable[33];

void GenerateAsymmetry(int Asymmetry, int SecondPole)
{
    double x = (double(Asymmetry)+1)/257 * 2 - 1;
    int ai = int(0.5 + 255 * (1- 1/(1000*x*x*x) + x - ((x >= 0)*2)));
    double as = fabs(double(ai) / 255);
    double dp = double(SecondPole) / 255;
    int ii;

    for (ii = 0 ; ii < 33 ; ++ii)
    {
        if(ai >= 0)
        {
            x = double(ii) / 32;
        }
        else
        {
            x = double(32 - ii) / 32;
        }
        int y = int((dp+(1-dp)*pow((fabs(1-dp-x)/dp), 3)) * (x*(as+1)/(as+x) ) *
            65535.0 + 0.5);
        y = y < 0 ? 0 : y > 65535 ? 65535 : y;

        if (ai < 0)
        {
            y = 65535 - y;
        }
        AsymmetryTable[ii] = y;
    }
}
```

9.3.3.2.3.3.13 ISS ISP GLBCE Iridix Forward and Reverse Perceptual Functions Look-up-tables

The iridix core works in a perceptually uniform space and thus when linear data is presented to the core it needs to be processed with special perceptual functions. These are implemented as two perceptual LUTs namely: Forward Perceptual LUT and Reverse Perceptual LUT. Each LUT is made up of sixty-five 32-bit words.

[GLBCE_REV_PERCEPT_LUT_00](#)

9.3.3.2.4 ISS ISP GLBCE Embedded Memory

GLBCE needs 2lines of line memories and 1 set of cache memories.

Table 9-205. ISS ISP GLBCE Memories

Memory	Qty	Type	Size	Clock	Description
glbce_line_mem	1	BRG	1408 x 64	FCLK	GLBCE line memory 2 lines x 32bit x 2816 required.
glbce_cache	8	BRG	16 bit x 1024	FCLK	GLBCE Cache memory (128 kbit) (8 set of 16 bit x 1024 entry) This memory is to OCP-Slave via MMR

9.3.3.2.5 ISS ISP GLBCE Programming Model

9.3.3.2.5.1 ISS ISP GLBCE Restriction

GLBCE has minimum input restriction of 480x240. The input must be at least this size.

After reset, GLBCE goes into initialization state of 554 clock cycles. While in this state, filtering flag is raised, and not input image may come into GLBCE module.

GLBCE LUTs must not be changed during the active frames. They can only be updated in vertical blanking. GLBCE_LUT_FI may be changed frame by frame depending on the GLBCE tuning method. Other LUTs (GLBCE_REV_PERCEPT_LUT_xx, GLBCE_FWD_PERCEPT_LUT_xx, and GLBCE_WDR_GAMMA_LUT_xx) are not expected to be updated dynamically except in very limited case.

9.3.3.2.5.1.1 ISS ISP GLBCE Recovery from Reset

GLBCE module needs certain number of cycles (554 cycles) of PCLK input after reset to regenerate the default table internally. Therefore, it requires special procedure after reset process (HW reset, ISP-Top level SW reset, and GLBCE level SW reset).

Typical procedure is as following, but other sources of PCLK may be used

- SW make sure PCLK is not provided to GLBCE right after reset (ISS Video Mux [VMUX] does not connect CAL and GLBCE)
- After GLBCE is reset, wait until GLBCE returns to normal status
- SW write [ISP_SWT_SEL](#)[9:8] GLBCE_SEL=1 (select GLBCE-CAL at ISP-Top) and Write "1" to [ISP5_CTRL](#)[19] GLBCE_CLK_ENABLE (Enable GLBCE clock)
- CAL starts generating PCLK in a dummy frame
- VMUX is switched to feed PCLK from CAL to GLBCE (This is after HS/VS, so GLBCE won't see them)
- Eventually GLBCE finishes initialization process, and generates filtering_done interrupt after ~5500 cycles (accurate cycle should be updated after DV completion). GLBCE is ready.
- SW detects filtering_done and stops PCLK generation by CAL
- SW may switch GLBCE_SEL to other values. Move to the next steps

9.3.3.2.5.1.2 General description of GLBCE processing

GLBCE block needs appropriate statistics information to be stored to its cache memory in prior to processing incoming frame. Usually, this takes a two-pass process.

1. GLBCE is configured for input frame-A
2. Frame-A is given to GLBCE
3. GLBCE processes the input frame-A
4. GLBCE generates statistic (statistics-A) data based on frame-A in vertical blanking period
5. (Optional process) statistics-A is read from cache memory and moved to SDRAM
6. GLBCE is configured for input frame-B
7. Frame-B is given to GLBCE

8. GLBCE processes the input frame-B with the statistics-A generated from frame-A
9. GLBCE generates statistics-B based on frame-B in vertical blanking period
10. (Optional process) statistics-B is read from cache memory and moved to SDRAM

Alternatively, GLBCE can process in the following manner

1. Pre-calculated Statistics-C is copied to GLBCE cache memory from SDRAM
2. GLBCE is programmed for input frame-D
3. Frame-D is given to GLBCE
4. GLBCE processes frame-D based on statistics-C
5. GLBCE generates statistics-D based on frame-D in vertical blanking period
6. (Optional process) statistics-D is read from cache memory and moved to SDRAM

In [Section 9.3.3.2.5.1.3](#), some examples closer to real world use cases are explained based on the above two processes.

9.3.3.2.5.1.3 Continuous Frame Processing

This is a very basic case, which does not need transferring statistics between cache memory and SDRAM. The most common example is video capture. In this case, the most straight forward way to run GLBCE, is to generate statistics from N-th frame, and apply it to (N+1)-th frame. The effect from using statistics of different frame should be small if the difference between frames is small. For example, it is expected this does not generate artifact, if the video frame rate is 30fps or larger. Below this rate, the single frame processing programming model explained in the next section should be considered.

In the case of continuous frame processing, GLBCE is operated in the following manner:

1. GLBCE is programmed for incoming frame
2. Input frame comes in
3. GLBCE processes Input frame based on the statistics from the previous frame
4. GLBCE generates statistics based on the current input frame in the vertical blanking period
5. Repeat Step 1 through 4 as required

For the first frame of a set of sequential frames, Strength parameter should be 0, so GLBCE does not affect the image based on wrong statistics. SW may need to increase the strength value gradually after the first frame.

9.3.3.2.5.1.4 Single Image Processing

For a single image, GLBCE needs to process the image twice, once for statistics generation, and once for actual GLBCE process.

1. GLBCE is configured for the input image.
2. The image is given to GLBCE. (Output image from GLBCE should be suppressed, for example, by disabling IPIPE.)
3. Statistics is generated in vertical blanking period.
4. The input image is given to GLBCE again. Output image with right GLBCE is generated.

Also, GLBCE can take in small size image in the first pass to reduce processing time.

5. A small size version (IMG-S) of the input image (IMG-IN) is generated.
6. GLBCE is configured for the small size image (IMG-S).
7. The small size image (IMG-S) is given to GLBCE.
8. Statistics for the small size image is generated in vertical blanking period.
9. GLBCE is configured for the original input image (IMG-IN).
10. The original input image (IMG-IN) is given to GLBCE.

9.3.3.3 ISS ISP NSF3V Functional Description

9.3.3.3.1 ISS ISP NSF3V Overview

The Noise Filter 3V is the on-the-fly advanced noise filter algorithm and edge enhancement. Noise filtering reduces or removes noise in images without blurring details or image features. It is particularly useful for processing images captured under low-light settings through an image signal processor (ISP).

Edge enhancement enhances the sharpness of the image. Edge enhancement is usually applied lightly to avoid processing artifacts in the eventual ISP output image.

Noise filtering and edge enhancement can be processed in separate passes or in a combined pass. Typically, in low-light areas of the image, noise filtering is applied. In bright areas of the image, edge enhancement is applied.

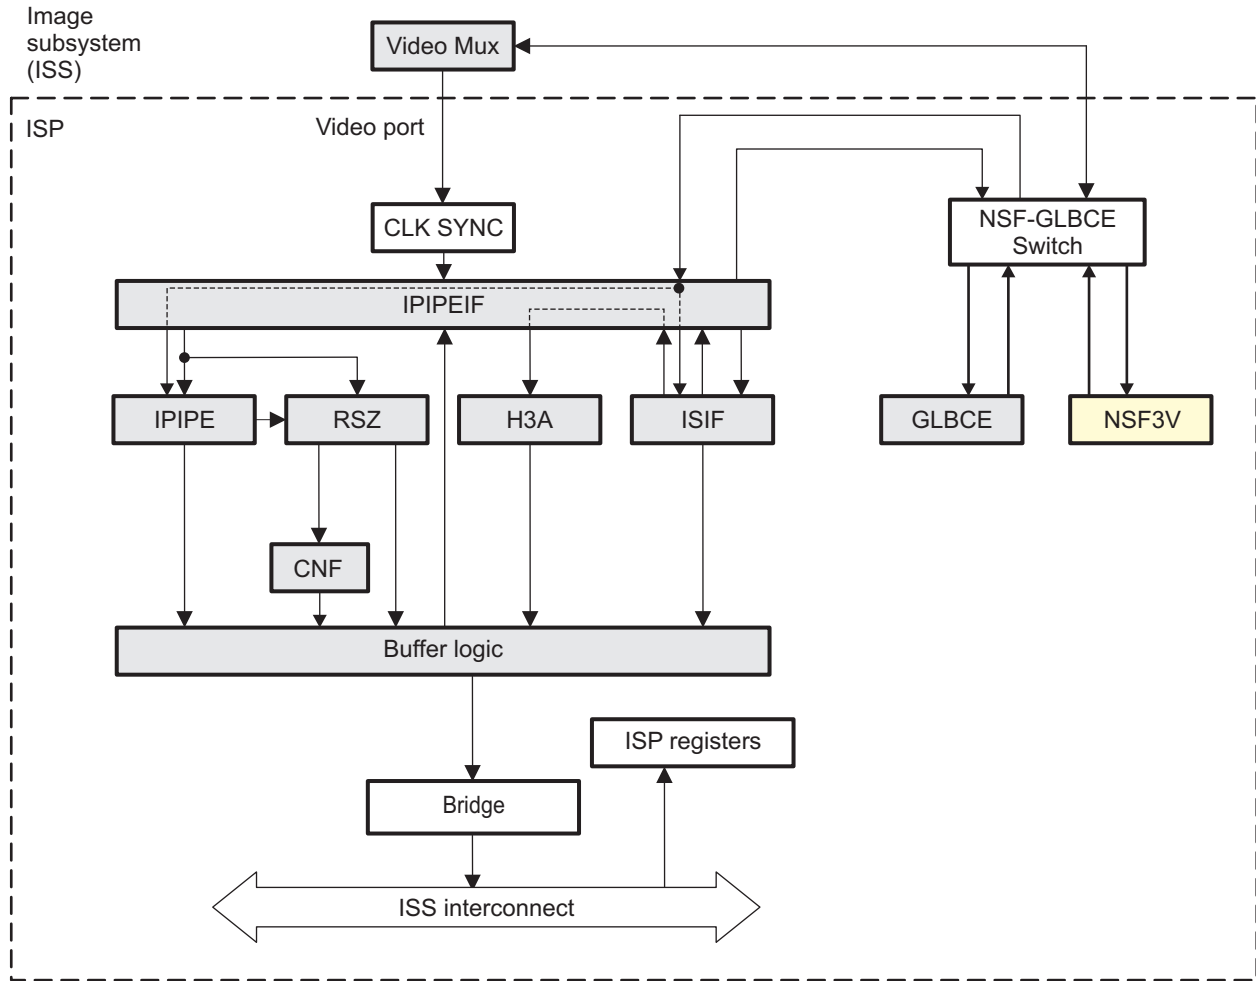

NSF3V operates on raw Bayer RGB data that it receives Bayer or YUV image data from IPIPEIF via Video Port, and processes the image and gives back the filtered image to ISIF. NSF3V is inserted into the path between IPIPEIF and ISIF. NSF3V can also work with CAL. Since no SDRAM round trip of data, the NSF3V can perform at 1pix/cycle. The module supports:

NSF3V functionality is not required to comply to any standard, as the noise filtering algorithm is proprietary.

- High-ISO Video Noise Filtering (NSF3V)
 - Up to 532 MPix/s
 - Bayer RGB, YUV422, and YUV420 formats
 - 12-bit datapath bit width
 - 2816 pixels input line memory size
 - Throughput of 1 data points per cycle, without the overhead
 - For Bayer, 1 pixel = 1 data point
 - For YUV422, 1 pixel = 2 data points
 - For YUV420, 1 pixel = 1.5 data points
 - Adaptive noise level threshold
 - Inter-color-luma-estimation affecting noise threshold
 - Soft thresholding
 - Edge enhancement
 - Radial shading gain
 - Desaturation for YUV
 - Use luma to drive chroma noise threshold in YUV422
 - Support output width = input width by replicating border pixels, requires at most 48 extra pixel of processing time per row
 - Separately replicate-or-trim support for left and right borders
 - Support output height = input height by replicating top/bottom border pixels, requires 7 extra rows of processing time
 - Interleaved processing options
 - Image framing
 - Single frame and video support, flexible interrupt configuration
 - When NSF3V and GLBCE are off, ISP is backward compatible with previous devices
 - DPC before NSF3V processing (DPC is switched between IPIPE and NSF3V)
 - NSF3-level image quality at 1080p120 throughput rate
 - NSF3 3x3-interleaving level image quality at 1080p60 throughput rate
 - Run in-line with ISP processing to reduce system traffic
 - Use luma to drive chroma thresholding for YUV422

[Figure 9-34](#) show the NSF3V module connections to other submodules of the ISP.

Figure 9-34. ISS ISP NSF3V High-Level Diagram

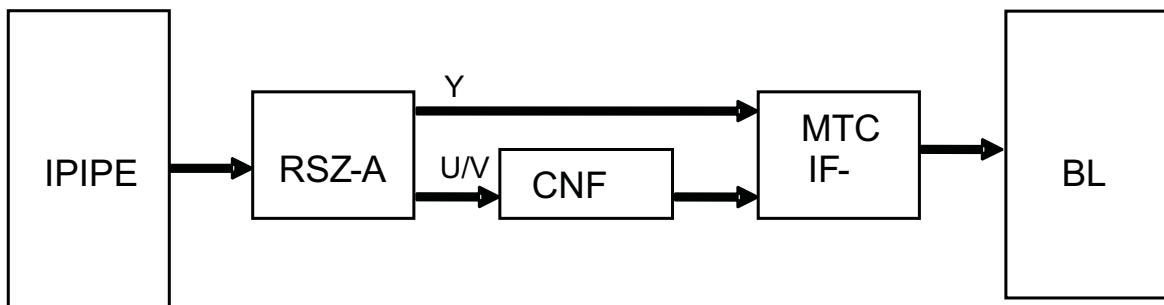

camisp-0036

NSF3V is instantiated 2 times in ISP. Full feature NSF3V, with all the operation modes, is used in the front end of ISP (as shown in the) and the integration supports the following dataflow options:

- CAL -> NSF3V -> CAL
- IPIPEIF -> NSF3V -> ISIF

The other instance are integrated in the backend of ISP, right after the ISP resizer output and inside the CNF block. The CNF block contains chroma downsampling and upsampling blocks before and after the NSF3V instance as shown in the [Figure 9-35](#).

Figure 9-35. ISS ISP NSF3V High-Level Diagram

camisp-810

9.3.3.3.2 ISS ISP NSF3V Register Shadowing

NSF3V module has a shadow copy of all the configuration registers, to allow changing the registers for the next frame, either for next single-frame or next frame in the video mode. A ready-to-reprogram interrupt (nsf3v_int_reprgm) is sent to indicate such time frame, and this shortly is after vertical start (VPin_VS) in input video port is received, and before the current frame is completed, indicated by nsf3v_int_outcmpl.

When hardware completes one frame of processing in the video mode, it clears NSF3V_CTRL[0] EN in the shadow copy only, so that software can indicate "this is the last frame" in the middle of the last frame processing, and the last frame would be processed to completion.

When hardware completes one frame of processing in one-shot mode, it clears NSF3V_CTRL[0] EN in both the config bus accessible copy and the shadow copy. This is to keep one-shot mode simple and truly one-shot; next frame should not be queued-up while the current frame is being processed

The configuration reprogramming time window from nsf3v_int_reprgm to nsf3v_int_outcmpl applies to all register fields except NSF3V_CTRL[0] EN in one-shot mode. Re-enabling NSF3V in one-shot mode (by writing 1 to NSF3V_CTRL[0] EN) should be performed AFTER nsf3v_int_outcmpl.

9.3.3.3.3 ISS ISP NSF3V Programming Model

9.3.3.3.3.1 ISS ISP NSF3V Initialization

Upon reset, NSF3V module is idle. When idle, NSF3V ignores VPIn, and does not send anything on VPout (VS/HS/VE/HE/EN/DATA = 0).

For single-frame mode of operation, software initializes or changes various parameters, with NSF3V_CFG[7] ONESHOT = 1, then writes 1 to the NSF3V_CTRL[0] EN bit to enable processing of one frame. After NSF3V_CTRL[0] EN is written 1, the module is ready to accept a new frame from the input video port.

For video mode of operation, software initializes or changes various parameters, with NSF3V_CFG[7] ONESHOT = 0, then writes 1 to the NSF3V_CTRL[0] EN bit to enable processing of image frames

To exit video mode, software writes 0 to NSF3V_CTRL[0] EN, and after the current frame processing is completed, NSF3V become idle again.

To program NSF3V to process image frame(s), image width/height, algorithm/processing features, and algorithm parameters should be programmed, then NSF3V_CTRL[0] EN bit written 1, then proper ISP/ISS components configured to start sending image frame(s) to NSF3V.

NSF3V processing/algorithm parameters are as follows:

- Mode of operation (NSF3V_CFG[3:0] MODE), with these options: {BAYER, BAYER_I2x2, BAYER_I3x3, YUV422, YUV420Y, YUV420UV, YUV422_I, YUV420Y_I, YUV420UV_I}.
- Border replication (NSF3V_CFG[11] LBORDER_REP, NSF3V_CFG[12] RBORDER_REP, NSF3V_CFG[13] TBORDER_REP, NSF3V_CFG[14] BBORDER_REP). When enabled, replicate left, right, top, and bottom borders, respectively, to selectively keep the border contribution to width/height, or reduce by the border width.
- Video port output data rate configured via NSF3V_VPOUT_CTRL[15:0] PCLK. Output EN signal would asserted and data (8/12/16-bit according to operation mode) at *functional clock* * NSF3V_VPOUT_CTRL[15:0] PCLK / 65536.

The following pseudo code sets a binary value on EN based on PCLK

```
ACC = 0;
while (1)
{
    wait_until_rising_edge_of_clock( );
    ACC += PCLK;
    EN = (ACC >= 65536);
    ACC = ACC % 65536;
}
```

CAUTION

Due to dependency, NSF3V requires horizontal and vertical blanking. Having blanking provided by the upstream module would suffice, but this adds inter-module dependency that can be difficult to debug. Having NSF3V drives its own output data rate would avoid this inter-module dependency.

NOTE: The SUSPEND signal from video port output would cause ignoring functional clock pulses and slowing down the output data rate.

- Edge enhancement enable ([NSF3V_CFG\[8\] EE_EN](#)).
- Radial shading gain enable ([NSF3V_CFG\[9\] SHD_EN](#)).
- Desaturation enable ([NSF3V_CFG\[10\] DESAT_EN](#)).
- YUV422 UV path hard thresholding enable ([NSF3V_CFG\[6\] HARD_THR_EN_422UV](#)).
- Image width and height in pixels ([NSF3V_DIM\[13:0\] IW](#), [NSF3V_DIM\[29:16\] IH](#)).

- Noise threshold piece-wise linear function parameters: NSF3V_TN_C[0..3][0..5].S[0..3][XYS], C[0..3] for the 4 color planes, and S[0..3] for the 4 segments. Together there are 4x4x3 = 48 parameters, each taking up 16-bit. Each color's S0_X is fixed at 0.
- Tn1-to-Tn2 and Tn3-to-Tn2 scaling factors ([NSF3V_TN_SCALE\[7:0\] TN1_TO_TN2](#) and [TN3_TO_TN2](#)).
- Soft thresholding function knee points u1, u2, u3 ([NSF3V_THR_KNEE.U\[1..3\]](#)).
- Soft thresholding suppression_max for each color/subband ([NSF3V_SUP_C\[0..3\]\[0..1\].L\[1..3\]_ \[LH, HH\]](#)), 4x3x2 = 24 parameters, each taking up a byte.
- Edge enhancement ee_max for each color/subband ([NSF3V_EE_C\[0..3\]_L\[1..3\]. \[LH, HH\]](#)), 24 parameters
- Desaturation parameters ([NSF3V_CFG\[10\] DESAT_EN](#), [NSF3V_DS_THR\[\] .THR1/2](#), [NSF3V_DS_SLOPE\[\] SLOPE1/2](#))

9.3.3.4 ISS ISP IPIPEIF Functional Description

9.3.3.4.1 ISS ISP IPIPEIF Overview

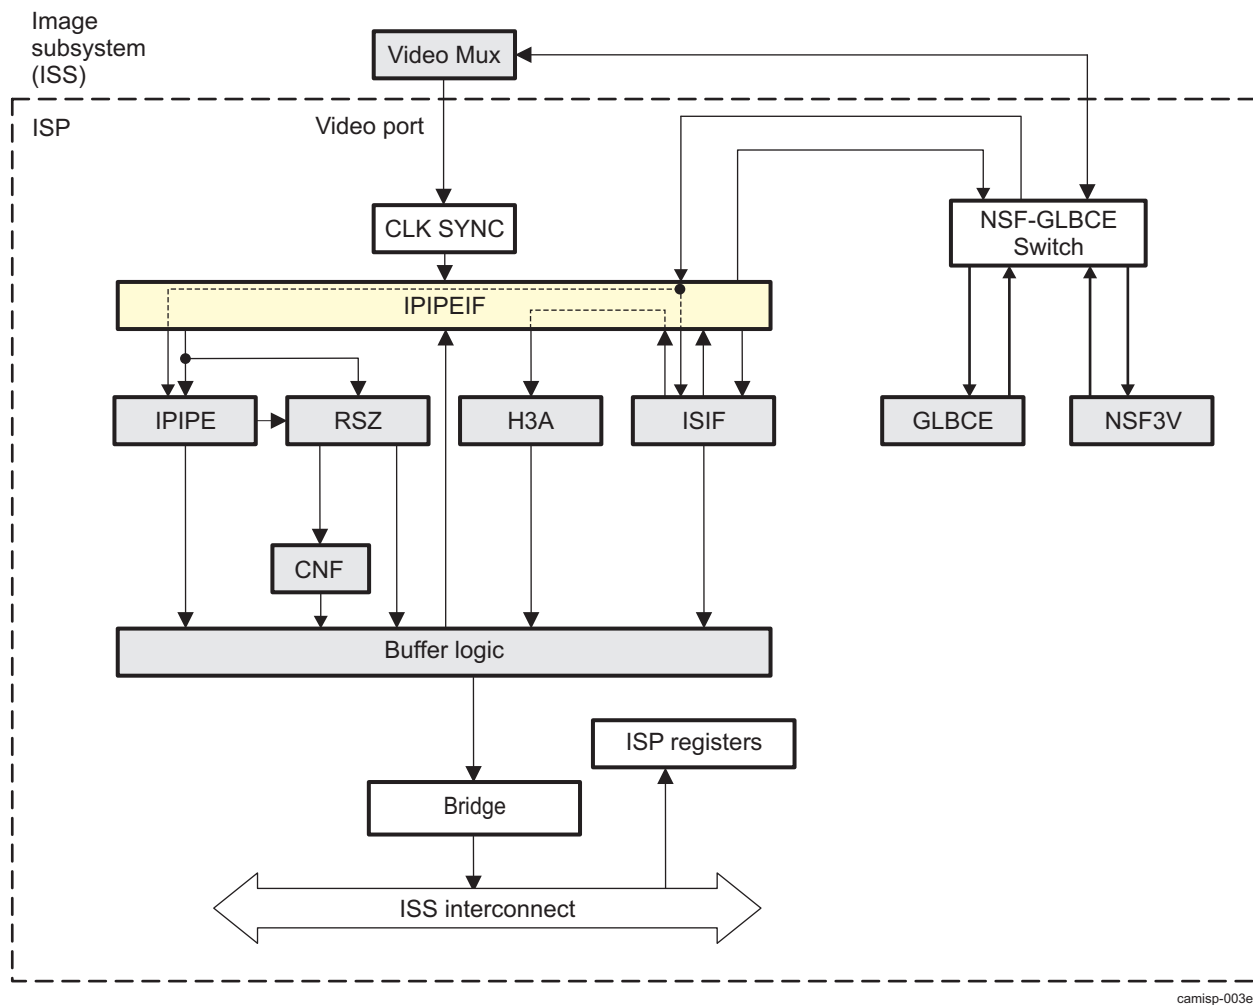

The IPIPEIF module provides data and synchronization signals (HD, VD) for the ISIF, IPIPE, RSZ, and H3A modules. The data source of this module is the VP, ISIF, or SDRAM using BL, and the selected data is output to ISIF, IPIPE, H3A, NSF-GLBCE switch, and RSZ. This module supports:

- Up to 16-bpp data on the VP
- Up to 532 MHz pixel clock on the VP, up to 8K x 8K imaging resolution
- RAW and YUV data formats on the VP and BL ports
- Dark-frame subtract of 8-bit RAW image stored in SDRAM from image from VP
- Dark-frame subtract of 8-bit RAW image stored in SDRAM from image from ISIF
- Dark-frame subtract of 8-bit RAW image from VP from image read from SDRAM through the BL
- Simple defect correction to prevent the subtraction of defect pixels
- 8-10, 8-12 DPCM of 10-8, 12-8 DPCM compressed data in SDRAM
- Simple and advanced DPCM predictor
- Inverse A-Law decompression of RAW data 10-8 A-Law compressed from SDRAM
- 8-bit, 12-bit unpacking of 8-bit, 12-bit packed SDRAM data
- Gain multiply for output data to the IPIPE module

- Horizontal Bayer rescaler in the data paths to the IPIPE and H3A modules: Supports (1, 2, 1) averager filter and supports horizontal pixel decimation
- Data rate control when reading data from RAM: Fraction clock divider
- (1, 2, 1) averager filter and supports horizontal pixel decimation in the data path to the IPIPE for YUV data.
- Support stalling of data processing in response to external request
- Issues stall signal to halt the up-stream module when necessary (IPIPEIF_INPUT_STALL)
- WDR Merging and WDR image split (Split 16-bit input into two 12-bit images)

Figure 9-36 show the IPIPEIF module connections to other submodules of the ISP.

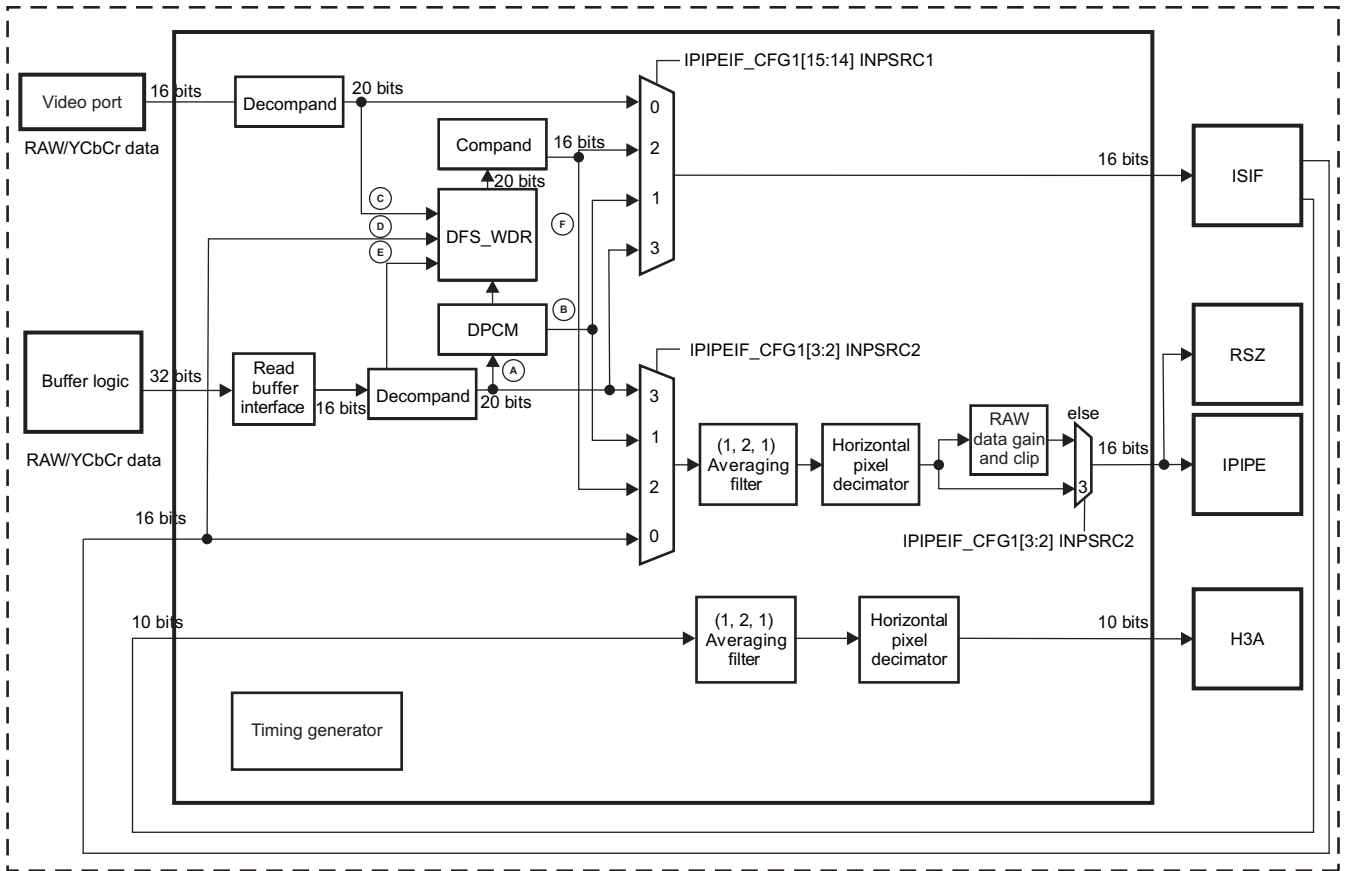

Figure 9-36. ISS ISP IPIPEIF High-Level Diagram

9.3.3.4.2 ISS ISP IPIPEIF Top-Level Block Diagram

The following sections describe the function of each subblock in the IPIPEIF, as shown in Figure 9-37.

Figure 9-37. ISS ISP IPIPEIF Top-Level Block Diagram

NOTE: When the IPIPEIF receives data from the VP, the timing generator must be configured for HD, VD, and WEN. For more information, see [Section 9.3.3.4.5, ISS ISP IPIPEIF Timing Generation](#).

9.3.3.4.3 ISS ISP IPIPEIF Input Interface

The IPIPEIF module comprises two major interface blocks: VP and BL. The data types can be RAW or YUV.

9.3.3.4.3.1 ISS ISP IPIPEIF Input From VP

The VP typically receives image data from the interfaces connected at ISS top level.

9.3.3.4.3.2 ISS ISP IPIPEIF Input From BL

The BL is the interface with the memory (SDRAM). In that case, the SDRAM address and line offset registers must be programmed in units of 32 bytes.

- SDRAM start address (byte) = $(\text{IPIPEIF_ADDRU}[10:0] \text{ADDRU}) \ll 16 + (\text{IPIPEIF_ADDRL}[15:0] \text{ADDRL})$
- SDRAM address offset (byte) = $\text{IPIPEIF_ADOFS}[11:0] \text{ADOFS}$

Two types of data can be stored in memory: pixel data and dark frame data.

For pixel data, the HD and VD signals are reconstructed with:

- IPIPEIF_HNUM

- [IPIPEIF_VNUM](#)
- [IPIPEIF_LPFR](#)
- [IPIPEIF_PPLN](#)

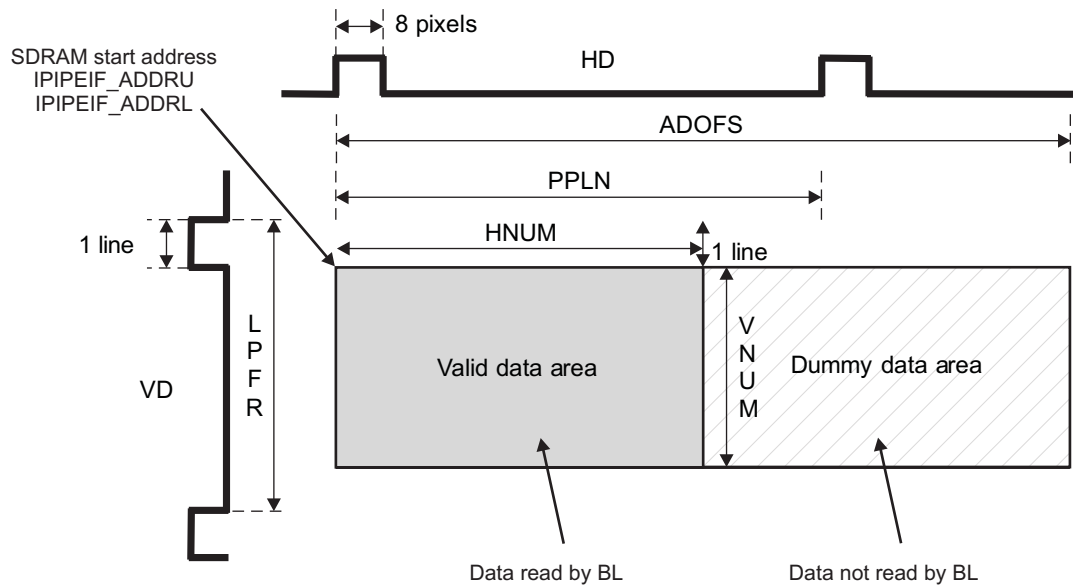

The [IPIPEIF_HNUM](#) and [IPIPEIF_VNUM](#) registers define the number of pixels per line and lines per frame to read from the SDRAM, and the [IPIPEIF_LPFR](#) and [IPIPEIF_PPLN](#) registers define the interval of VD and HD, respectively.

Vertical blanking for the frame is defined with the following equation: $IPIPEIF_LPFR - IPIPEIF_VNUM - 1$.

Horizontal blanking for the frame must be at least eight ISP_FCLK cycles, and is defined with the following equation: $IPIPEIF_PPLN - IPIPEIF_HNUM > 7$.

[Figure 9-38](#) shows the global frame definition for all SDRAM input modes, except for dark frame subtract.

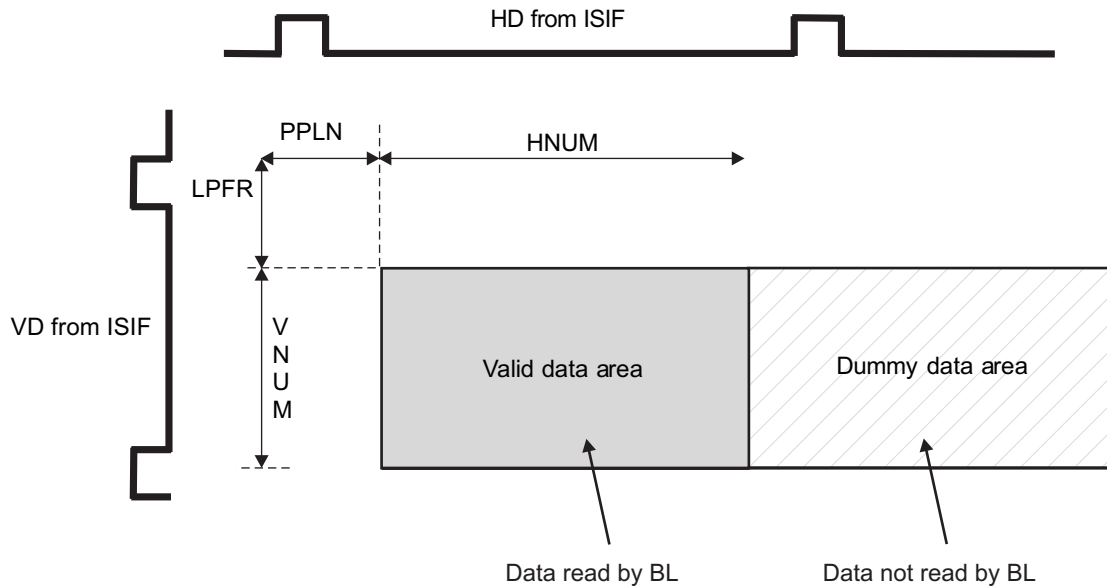

Figure 9-38. ISS ISP IPIPEIF Global Frame Definition in SDRAM Input Modes (Except Dark Frame)

camss-031

For dark frame data, the HD and VD signals come from the VP through the ISIF. The [IPIPEIF_PPLN](#) and [IPIPEIF_LPFR](#) registers must be used to indicate the horizontal and vertical start position of the subtraction from the ISIF data, as shown in [Figure 9-39](#). The value of the [IPIPEIF_LPFR\[12:0\]](#) LPFR bit field must be greater than 0 because the first line from the VP or ISIF cannot be subtracted from. The [IPIPEIF_HNUM](#) and [IPIPEIF_VNUM](#) registers must be used to set the number of valid pixels horizontally and the number of valid lines vertically.

Figure 9-39. ISS ISP IPIPEIF Global Frame Definition in Dark Frame Subtract Mode

camss-034

9.3.3.4.3.2.1 ISS ISP IPIPEIF Double-Buffer Input Function When Reading From BL

The IPIPEIF module supports a double-buffer input function. This feature is most useful when SDRAM space is limited, because it enables to read continuously from two buffers and to push data to the rest of the ISP (ISIF, H3A, etc.) for further processing.

Consider the following configuration where data are read from two buffers, A and B. The intent is not only to read continuously from these buffers but also to ensure that the ISP modules consider the data as being from the same frame; that is, VD is generated the first time buffer A is read, but it must not toggle until all the frames are read.

The IPIPEIF module can mask the VD sync signal by setting the `IPIPEIF_ENABLE[1] SYNCOFF` bit such that the IPIPEIF module drives the data to the ISP modules as if it is a continuous frame data.

In the following example, there are 16 lines per trigger and input circular addressing. $VNUM = 16$ (see Figure 9-38), and the VD signal is generated only for the first frame (see Figure 9-40).

Figure 9-40. ISS ISP IPIPEIF Double-Buffer Functionality

camss-615

9.3.3.4.4 ISS ISP IPIPEIF Data Path Selection

The data path configuration through the IPIPEIF module is set with the [IPIPEIF_CFG1\[15:14\] INPSRC1](#) and [IPIPEIF_CFG1\[3:2\] INPSRC2](#) bit fields. [Table 9-206](#) lists the possible combinations for these two bit fields.

Table 9-206. ISS ISP IPIPEIF IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 Possible Combinations

IPIPEIF_CFG1[15:14] INPSRC1	IPIPEIF_CFG1[3:2] INPSRC2	Description	Common Use
0	0	This data path is described in Section 9.3.3.4.4.1, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0.	Video record, view finder, on-the-fly still image capture applications
0	1	This data path is described in Section 9.3.3.4.4.2, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1.	Memory-to-IPIPE-to-memory operation
0	2	This data path is described in Section 9.3.3.4.4.3, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2.	Image capture with on-the-fly dark frame subtraction

Table 9-206. ISS ISP IPIPEIF IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 Possible Combinations (continued)

IPIPEIF_CFG1[15:14] INPSRC1	IPIPEIF_CFG1[3:2] INPSRC2	Description	Common Use
0	3	This data path is described in Section 9.3.3.4.4.4 , <i>ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3</i> .	On-the-fly data acquisition done in VP, forwarded to the ISIF, and then to the H3A through IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory YUV4:2:2 or RAW data processing with the IPIPE and RSZ modules from memory to memory fetched by IPIPEIF
1	0	This data path is described in Section 9.3.3.4.4.5 , <i>ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0</i> .	Memory-to-ISIF-to-memory operation
1	1	This data path is possible but there is no use case associated.	N/A
1	2	This data path is not supported.	N/A
1	3	This data path is not supported.	N/A
2	0	This data path is described in Section 9.3.3.4.4.6 , <i>ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0</i> .	Dark frame subtraction is performed and data sent to the ISIF module for further processing, back to IPIPEIF, and then to IPIPE and RSZ.
2	1	This data path is not supported.	N/A
2	2	This data path is not supported.	N/A
2	3	This data path is not supported.	N/A
3	0	This data path is described in Section 9.3.3.4.4.7 , <i>ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0</i> .	Memory-to-ISIF-to-memory operation
3	1	This data path is not supported.	N/A
3	2	This data path is not supported.	N/A
3	3	This data path is possible but there is no use case associated.	N/A

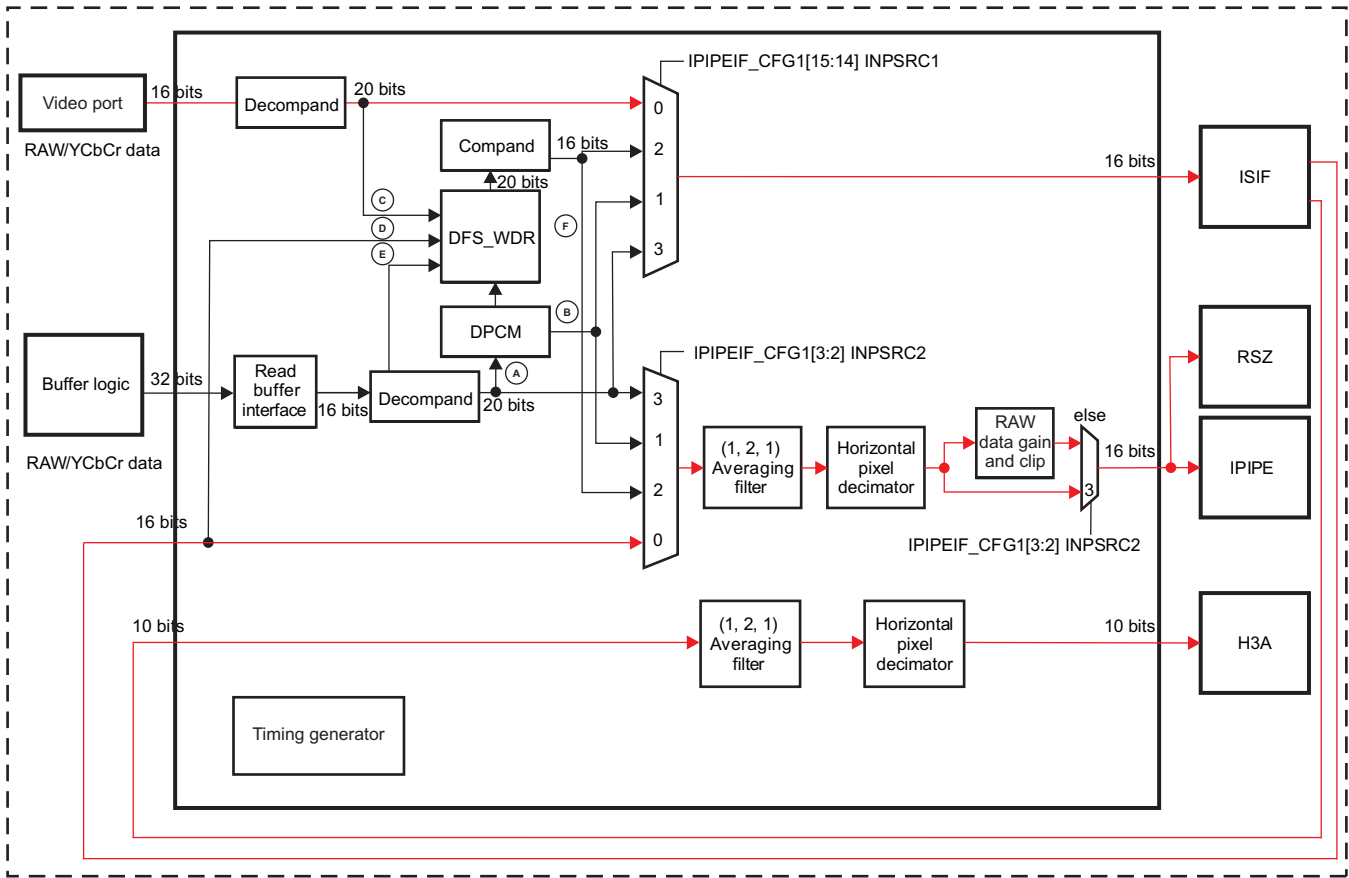

9.3.3.4.4.1 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0

Set the [IPIPEIF_CFG1\[15:14\] INPSRC1](#) bit field to 0 and the [IPIPEIF_CFG1\[3:2\] INPSRC2](#) bit field to 0.

This configuration can be used for the video record, viewfinder, and on-the-fly still image capture applications. The full ISP processing capability is used in a single pass.

[Figure 9-41](#) shows the data path.

Figure 9-41. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0 Data Path

camss-603b

9.3.3.4.4.2 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1

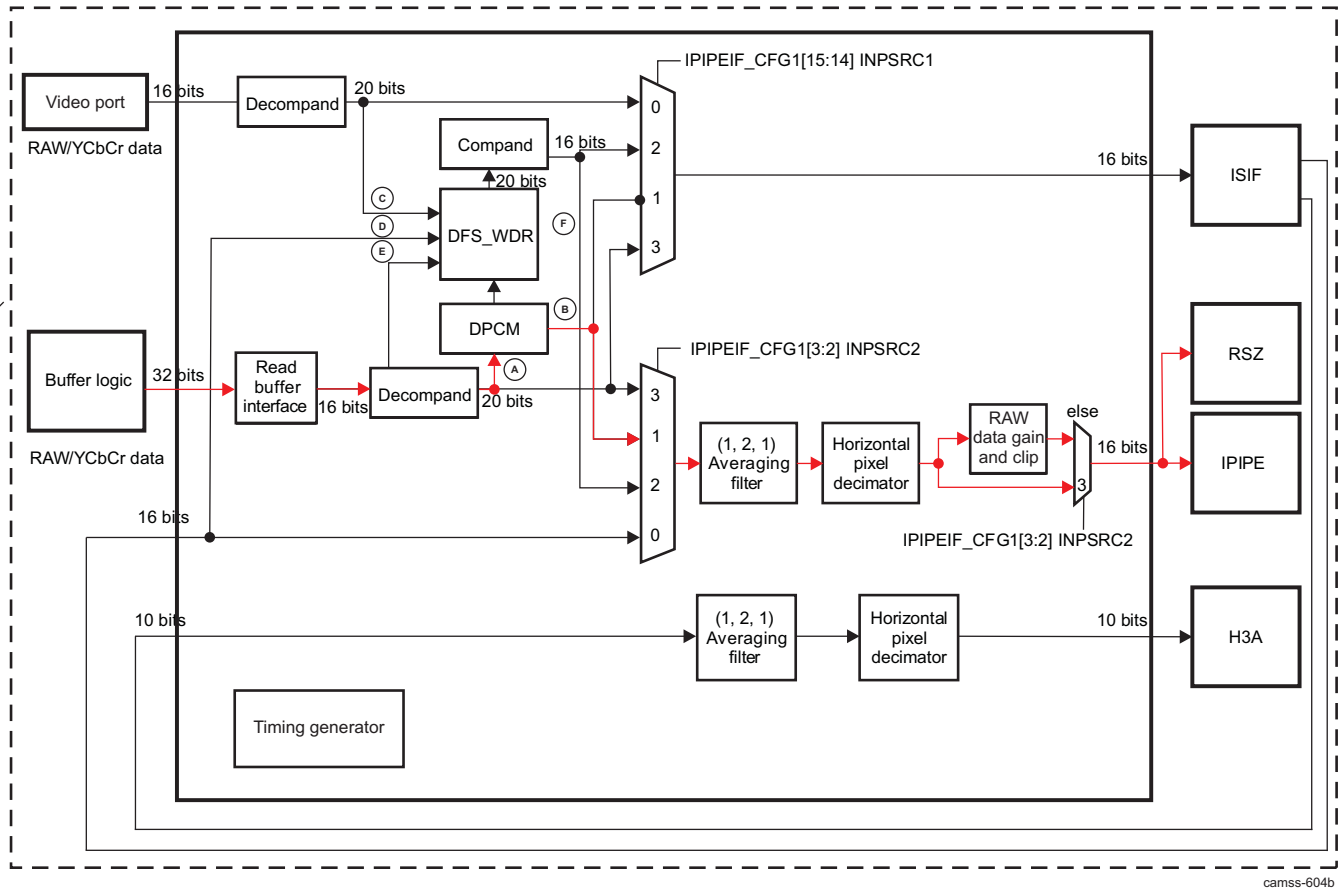

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 0 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 1.

This configuration can be used to process data with the IPIPE module from memory to memory. The data stored in SDRAM can be decompressed (A-law or DPCM) before being forwarded to the IPIPE module.

NOTE: In this configuration, the ISIF and H3A modules are assumed to be disabled.

Figure 9-42 shows the data path.

Figure 9-42. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1 Data Path

camss-604b

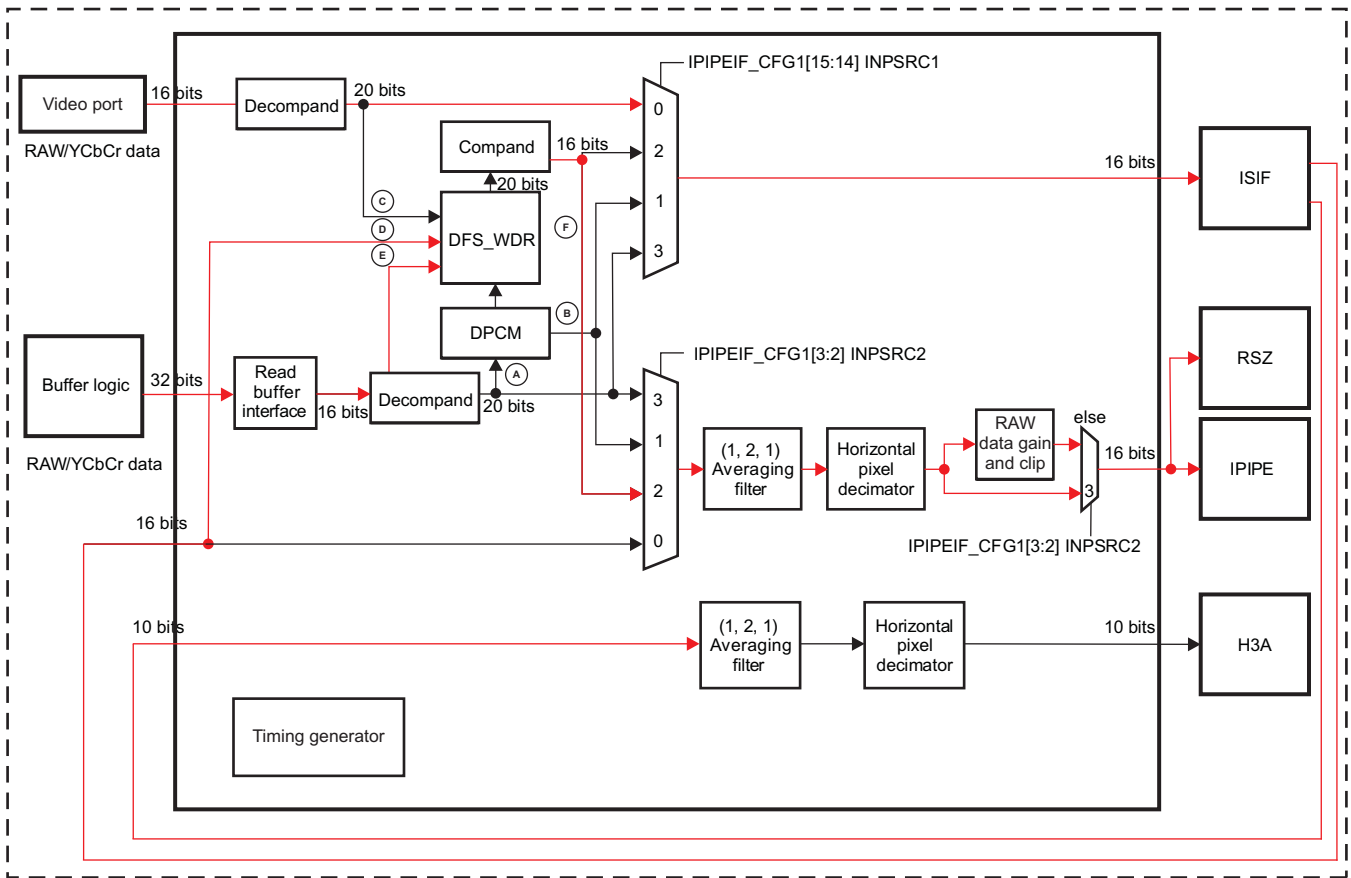

9.3.3.4.4.3 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 0 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 2.

This configuration can be used for image capture with on-the-fly dark-frame subtraction. In the first case, the dark frame can come from BL and data from the ISIF. In the second case, the dark frame can come from the VP and data from BL.

Figure 9-43 shows the data path.

Figure 9-43. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2 Data Paths

camss-610b

9.3.3.4.4 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3

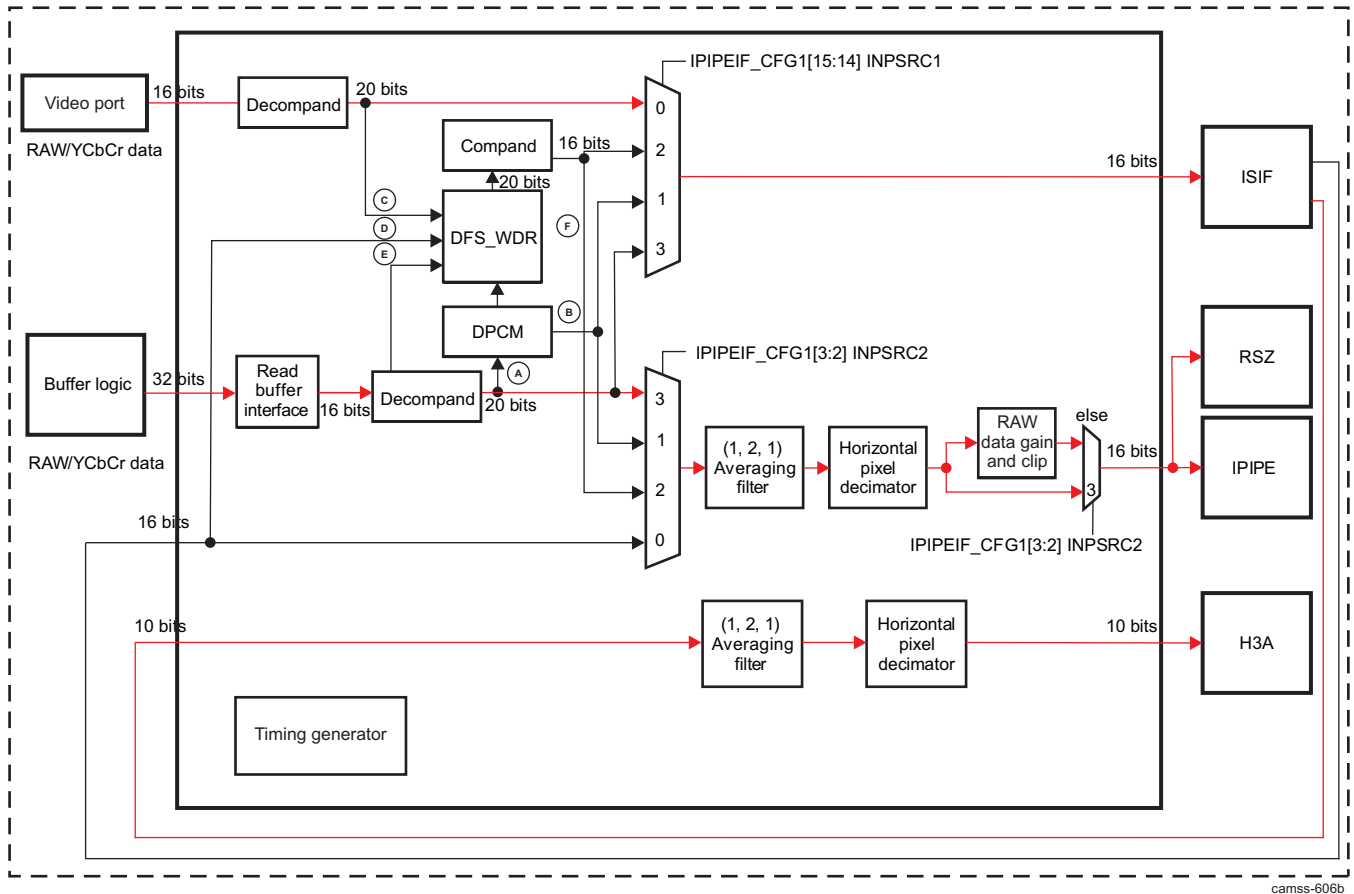

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 0 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 3.

In the first case, on-the-fly data acquisition is done with the VP, forwarded to the ISIF, and then sent to the H3A through the IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory.

In the second case, the configuration can be used to process YUV4:2:2 or RAW data with the IPIPE and RSZ modules from memory-to-memory. The YUV4:2:2 or RAW data stored in the SDRAM is fetched and forwarded to the IPIPE and RSZ modules. ISIF and H3A are assumed to be disabled in this configuration.

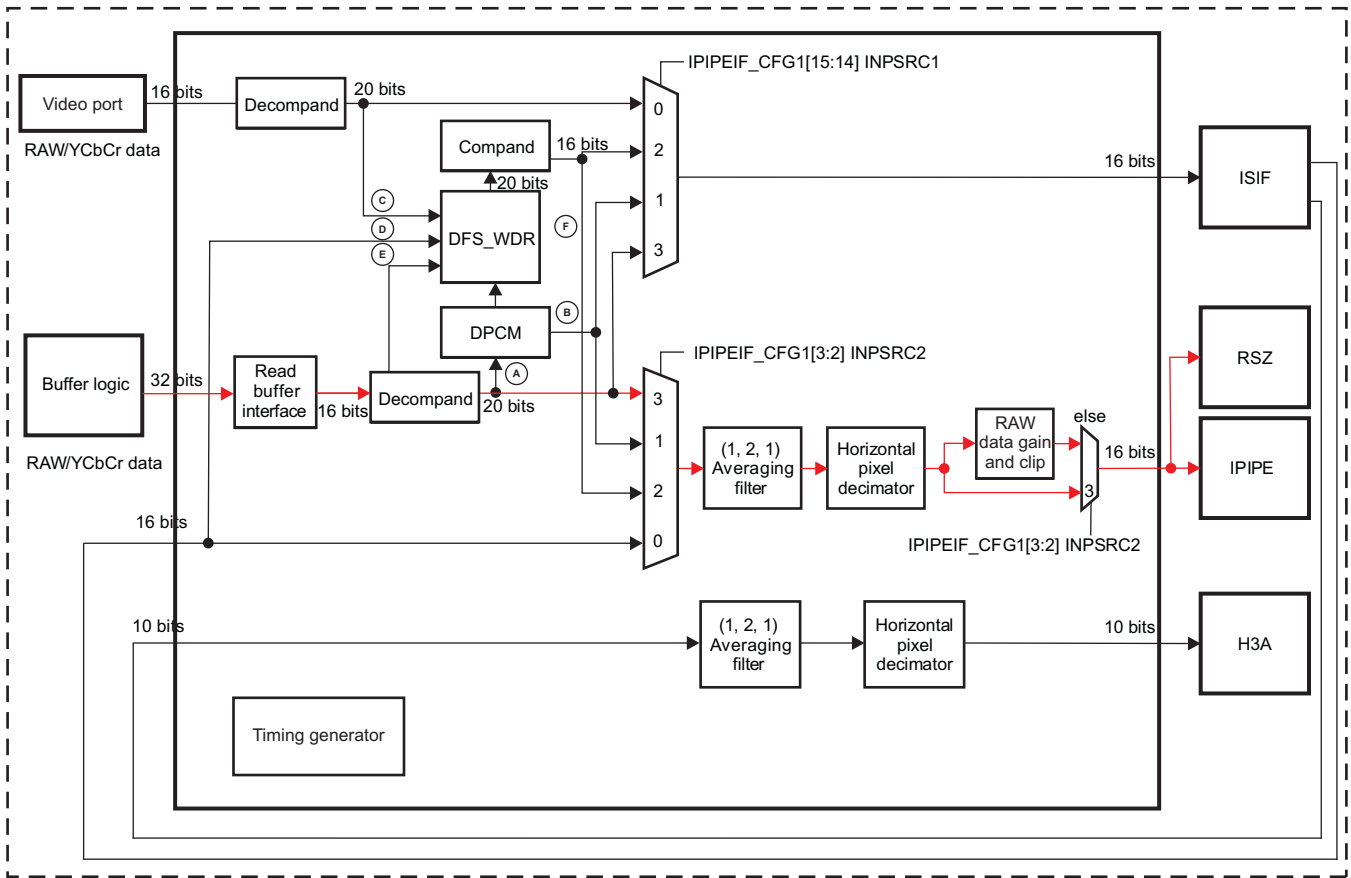

Figure 9-44 and Figure 9-45 show the two possible data paths.

Figure 9-44. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3 Data Paths: First Case

camss-606b

Figure 9-45. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3 Data Paths: Second Case

camss-605b

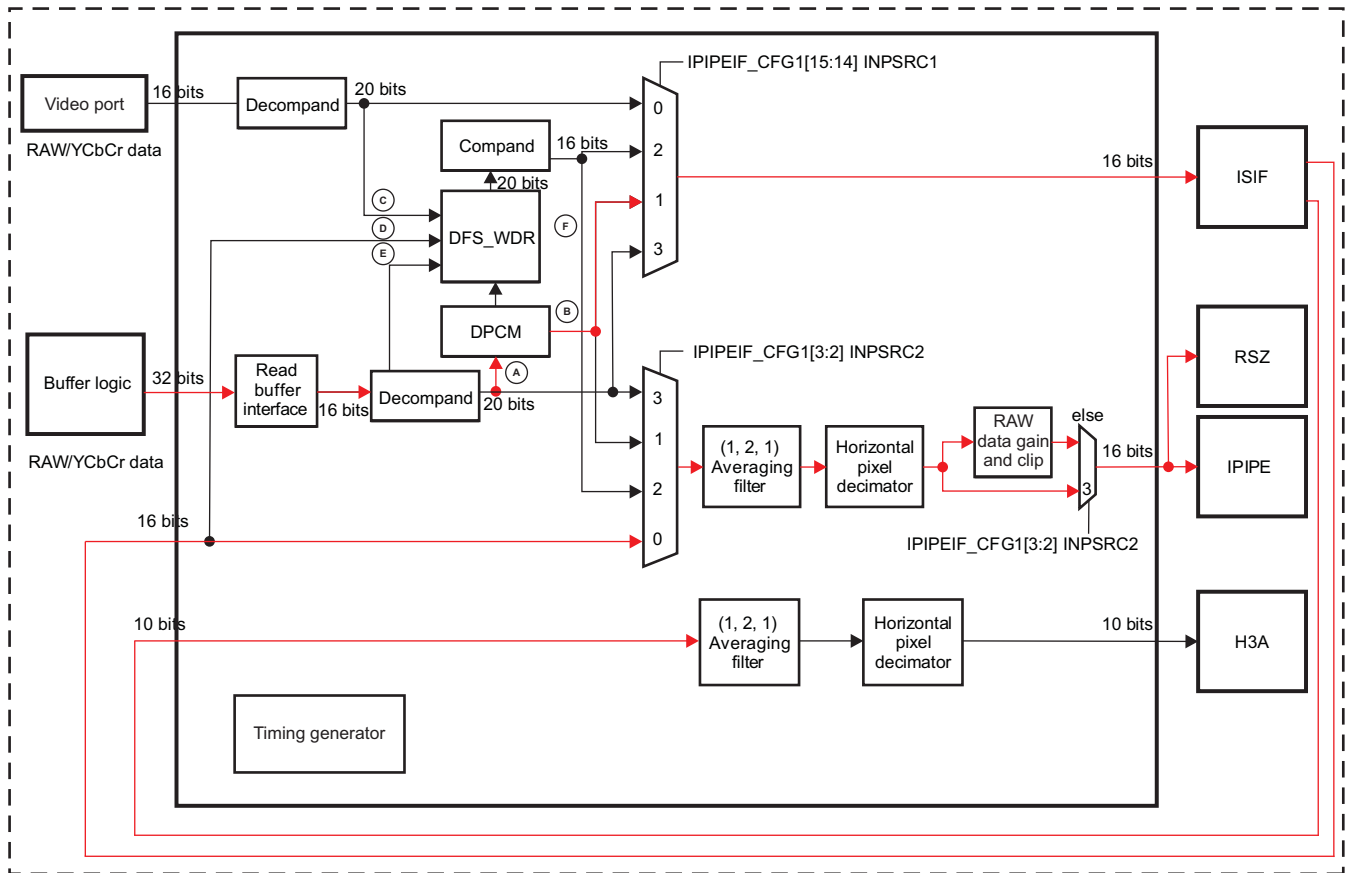

9.3.3.4.4.5 ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 1 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 0.

This configuration is a memory-to-memory operation. RAW data is read by the BL interface, decompressed, and pushed to the ISIF. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE and H3A modules.

Figure 9-46 shows the data path.

Figure 9-46. ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0 Data Path

camss-607b

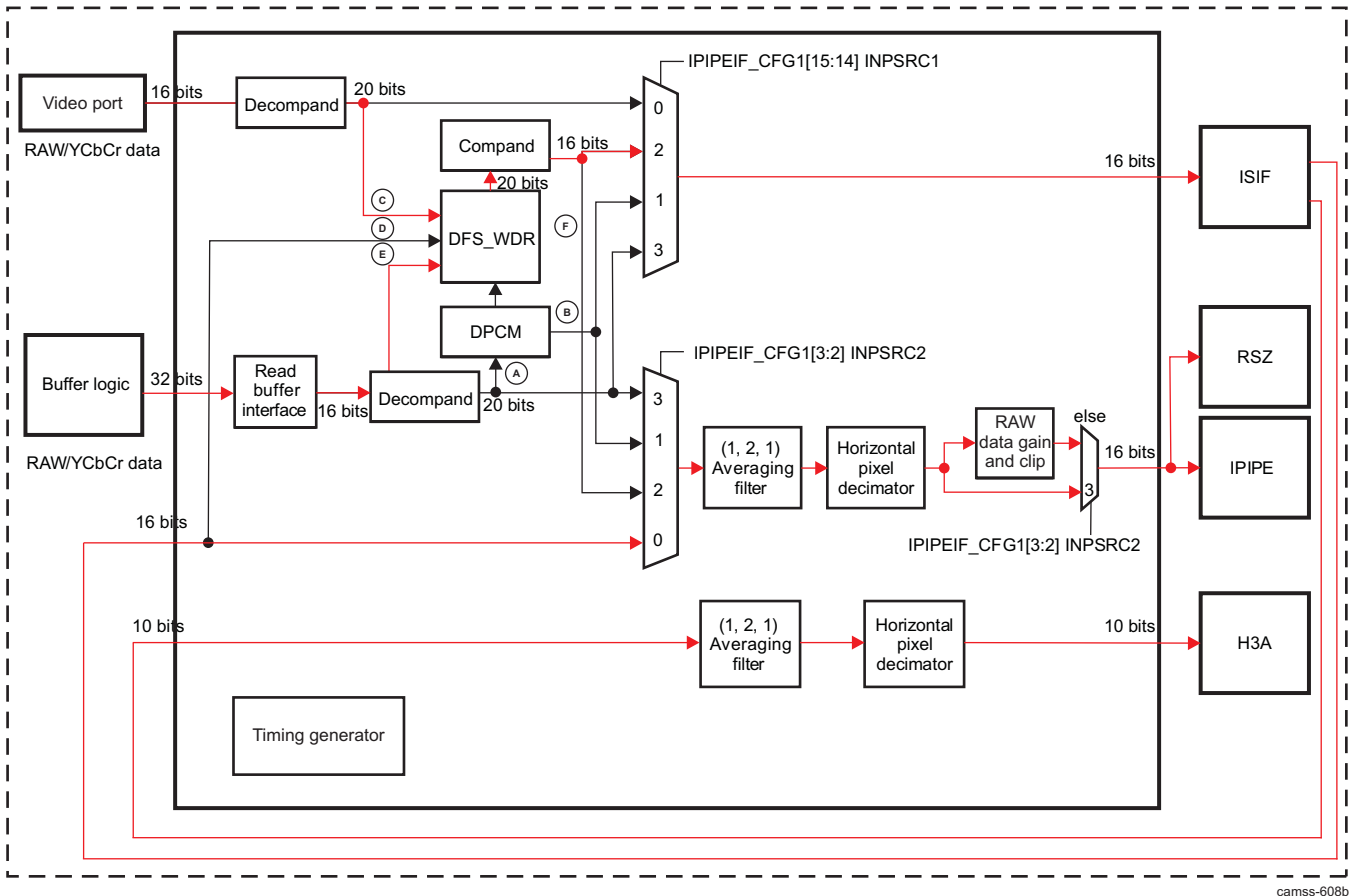

9.3.3.4.4.6 ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0

Set the `IPIPEIF_CFG1[15:14]` INPSRC1 bit field to 2 and the `IPIPEIF_CFG1[3:2]` INPSRC2 bit field to 0.

In this configuration, dark frame subtraction is performed and data is sent to the ISIF module. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ modules. There are two possible dark frame subtractions: the first is with data coming from the VP and the dark frame coming from BL; the second is with data coming from BL and the dark frame coming from the VP.

Figure 9-47 shows the data path.

Figure 9-47. ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0 Data Path

camss-608b

9.3.3.4.4.7 ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0

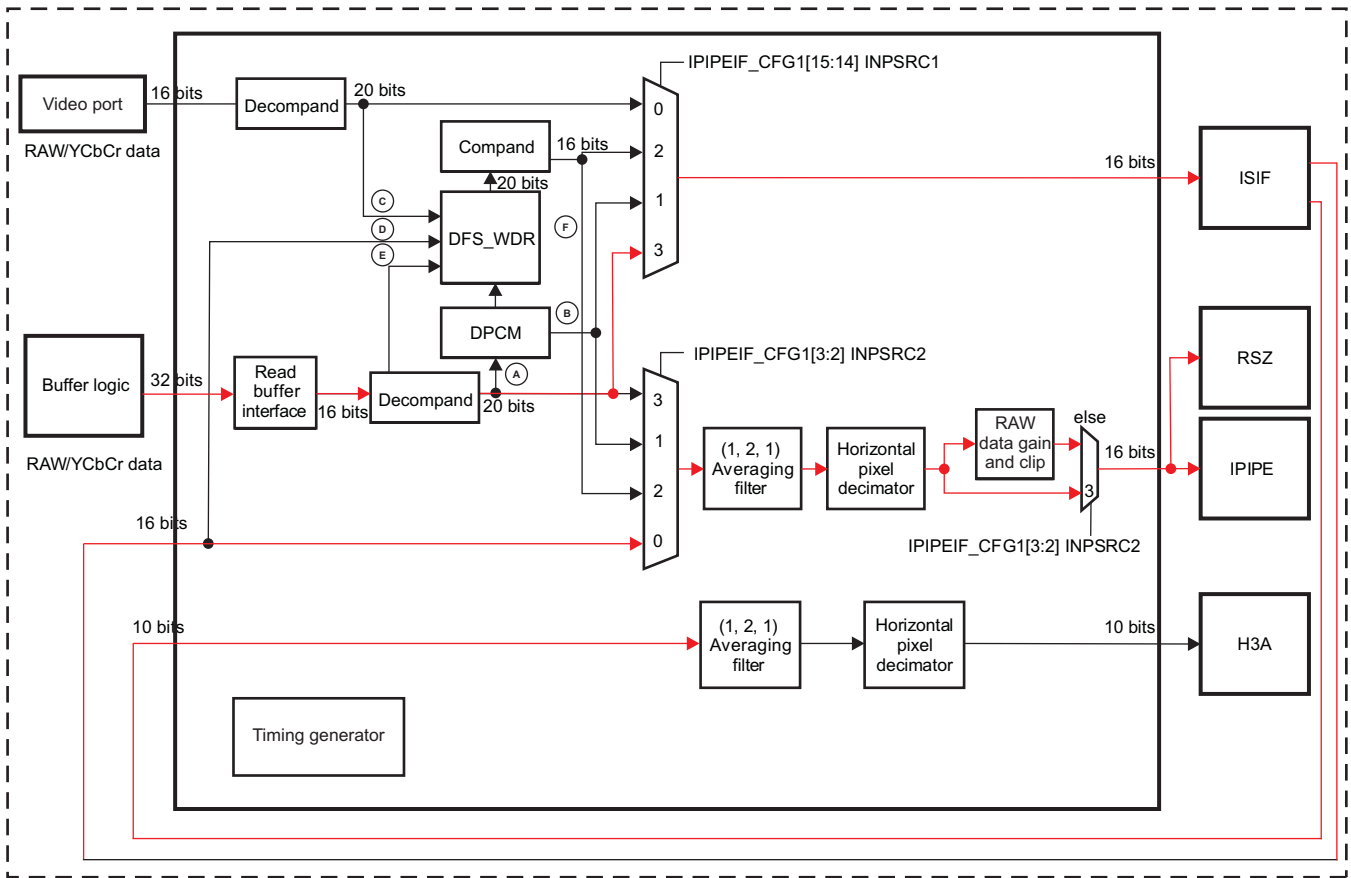

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 3 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 0.

This configuration is a memory-to-memory operation. Data is loaded from the SDRAM. Input data is expected as 16 bpp. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ module.

In this configuration data is assumed to be YUV only, and H3A and RAW data gain are assumed to be disabled.

Figure 9-48 shows the data path.

Figure 9-48. ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0 Data Path

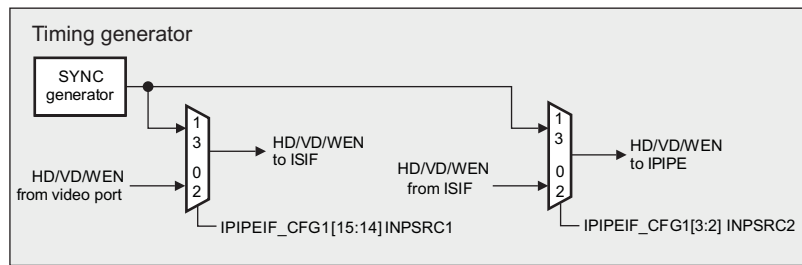

camss-609b

9.3.3.4.5 ISS ISP IPIPEIF Timing Generation

Figure 9-49 shows the ISS ISP IPIPEIF timing generator submodule.

Figure 9-49. ISS ISP IPIPEIF Timing Generator Submodule

camss-602

When the IPIPEIF module input source is from the VP (`IPIPEIF_CFG1[15:14] INPSRC1 = 0 or 2`) or the ISIF (`IPIPEIF_CFG1[3:2] INPSRC2 = 0 or 2`), the `IPIPEIF_CFG1[10] CLKSEL` bit must be set to 0 so that data is latched using the PCLK, HD, and VD signals from the VP.

When the IPIPEIF module input source is not from the VP (`IPIPEIF_CFG1[15:14] INPSRC1 = 1 or 3`), the `IPIPEIF_CFG1[10] CLKSEL` bit must be set to 1 so that the IPIPEIF module generates its proper PCLK, HD, and VD signals (through the use of the SYNC generator). The `IPIPEIF_CLKDIV` register is then used to select a divide ratio of the SDRAM (DMA) clock for the pixel clock frequency, which is used to clock the data into the PCLK. See [Section 9.3.3.4.5.1, ISS ISP IPIPEIF Fractional Clock Divider](#).

When the `IPIPEIF_CFG1[15:14] INPSRC1` or `IPIPEIF_CFG1[3:2] INPSRC2` bit field is not set to 0, the IPIPEIF SDRAM data reading and timing generation can be enabled (`IPIPEIF_ENABLE[0] ENABLE`) in one-shot mode or continuous mode (`IPIPEIF_CFG1[0] ONESHOT`).

9.3.3.4.5.1 ISS ISP IPIPEIF Fractional Clock Divider

When the input data of the IPIPEIF module does not come from the VP but from memory, it is useful to have control of the rate at which the data is fetched from memory to avoid overflow conditions or to avoid peak bandwidth requirements. The `IPIPEIF_CFG1[10] CLKSEL` bit is equal to 1 for fractional divider use.

The ISP clock `ISP_FCLK` is divided to generate the pixel clock, which goes to the ISIF and IPIPE modules when data is read from memory (`IPIPEIF_CFG1[15:14] INPSRC1 = IPIPEIF_CFG1[3:2] INPSRC2 = 1` or 3). The `IPIPEIF_CLKDIV` register selects the divider ratio: M and N values in the `IPIPEIF_CLKDIV[15:0] CLKDIV` bit field.

Given an input clock of clock rate `ISP_FCLK`, the fractional clock divider generates an output clock with average clock rate f_{OUT} .

Where $f_{OUT} = ISP_FCLK \times M/N$, and $M = 1$ through 256, and $N = 1$ through 256.

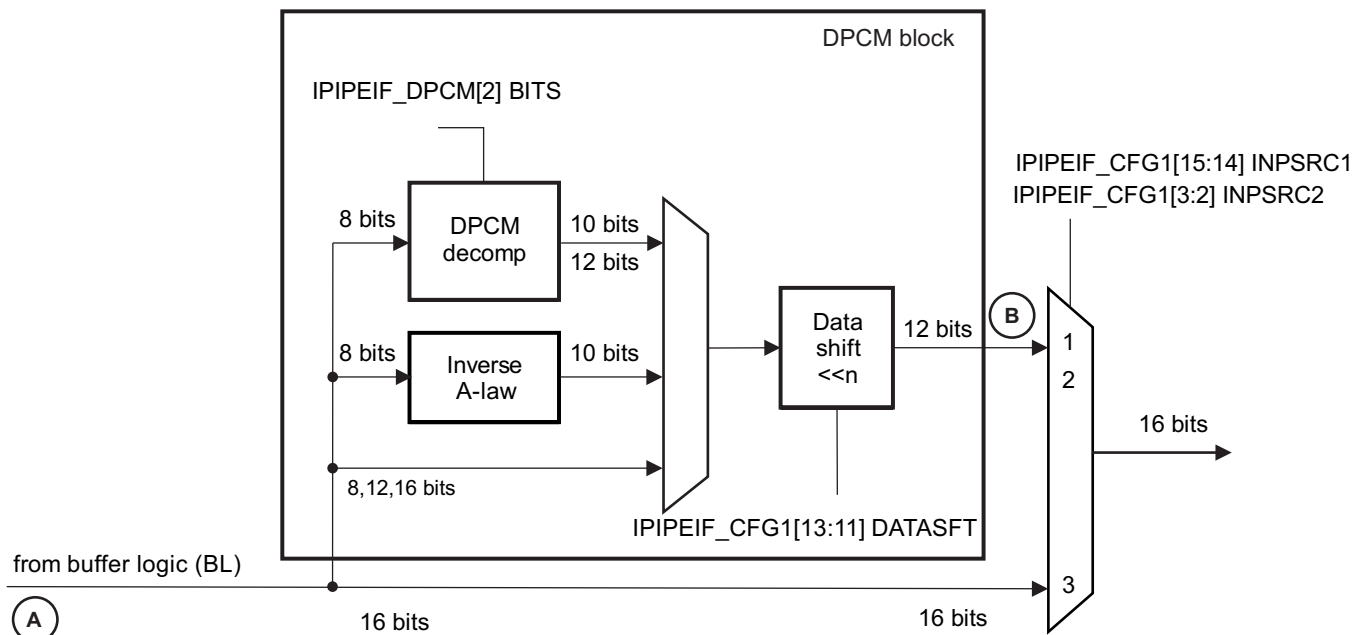

The fractional clock divider logic is synchronous and uses only the positive clock edge of the input clock.

9.3.3.4.6 ISS ISP IPIPEIF Decompression (DPCM) Subblock: Unpack and Decompression Function

The IPIPEIF module can read RAW data from memory. The RAW data can be previously packed/compressed into memory. Unpack, A-Law decompression, and DPCM decompression are available in the IPIPEIF module.

Figure 9-50 shows the DPCM subblock.

Figure 9-50. ISS ISP IPIPEIF DPCM Subblock

camss-032

Table 9-207 provides the possible configuration of the DPCM block.

Table 9-207. ISS ISP IPIPEIF DPCM Block Possible Configuration

Number of Bits per Pixel at DPCM Block Input	Number of Bits per Pixel at DPCM Block Output	Description	Registers
16	16	It can correspond to YUV4:2:2 or RAW16 data.	IPIPEIF_CFG1 [9:8] UNPACK = 0x0 In this configuration, IPIPEIF_CFG1 [3:2] INPSRC2 = 0x3. In this configuration data bypasses the DPCM block.
8	8	PACK8: YUV	IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x0 IPIPEIF_CFG1 [13:11] DATASFT = 0x01 In this configuration an 8-bit packed RAW data is used in DFS mode or YUV4:2:0 pass through. (See Section 9.3.3.4.14 , <i>ISS ISP IPIPEIF YUV4:2:2 8-bits Packed Data Input Coming From ISIF Module.</i>)
8	10	DPCM10: The 8-bit input data are DPCM-decompressed in 10 bits.	IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x1 IPIPEIF_DPCM [2] BITS = 0x0 Set the IPIPEIF_DPCM [1] PRED ^{(1) (2)} IPIPEIF_CFG1 [13:11] DATASFT = 0x2
8	12	DPCM12: The 8-bit input data are DPCM-decompressed in 12 bits.	IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x1 IPIPEIF_DPCM [2] = 0x1 Set the IPIPEIF_DPCM [1] PRED ^{(1) (2)} IPIPEIF_CFG1 [13:11] DATASFT = 0x0
8	10	ALAW10: The 8-bit input data were previously A-law compressed. The 8 bits are A-law decompressed and padded with 0.	IPIPEIF_CFG1 [9:8] UNPACK = 0x2 IPIPEIF_CFG1 [13:11] DATASFT = 0x2
12	12	PACK12: The input is coded on 12 bits and is packed in the SDRAM. This mode is compatible with the ISIF module packing capability. If inverse A-law and DPCM decompression are not enabled, the data read from the SDRAM can be shifted by the IPIPEIF_CFG1 [13:11] DATASFT bit field to select which 12 bits to use. MSB input data bit must be shifted such that it corresponds to bit 11 after the shift.	IPIPEIF_CFG1 [9:8] UNPACK = 0x3 Set the IPIPEIF_CFG1 [13:11] DATASFT

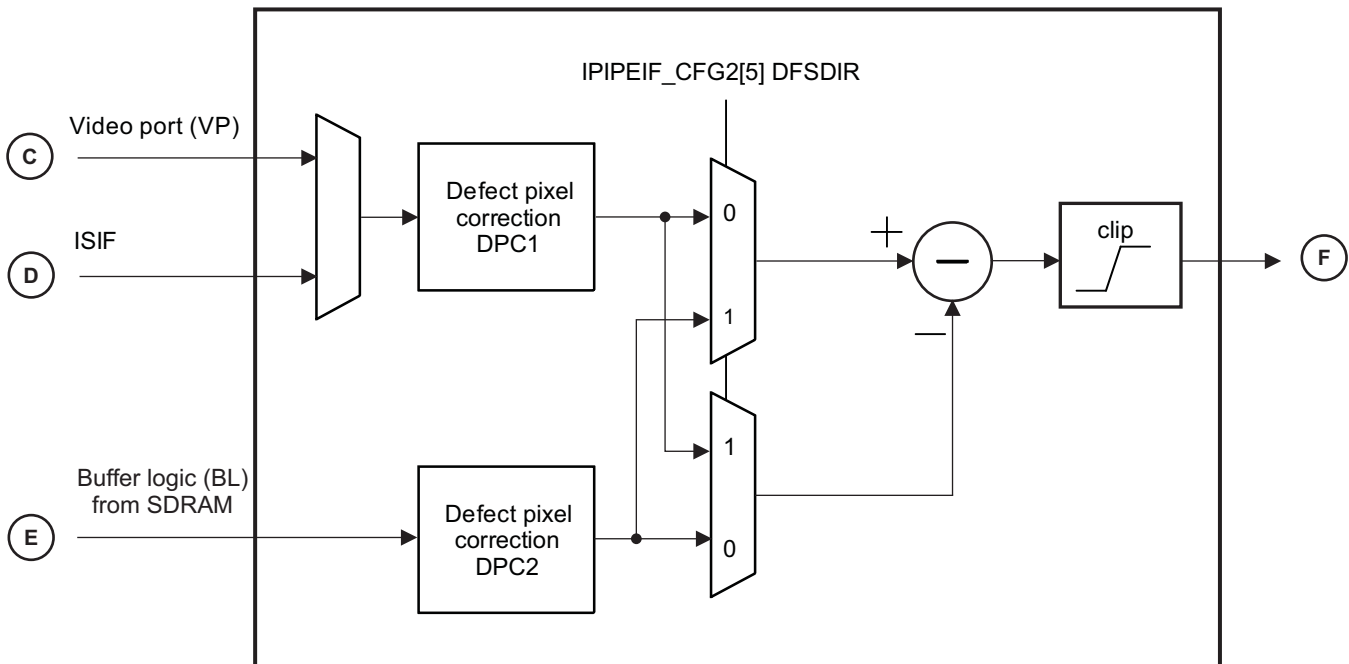

⁽¹⁾ The simple predictor uses only the value of the previous same color component as a prediction value. Therefore, only 2-pixel memory is required. It is typically used for 10–8–10 or 12–8–12 bit conversions.

⁽²⁾ The advanced predictor uses four previous pixel values, when the prediction value is evaluated. This means that the values of the other color components are also used, when the prediction value is defined. Therefore, the advanced predictor is slightly better than the simple predictor but consumes more power and memory. It can, however, improve image quality. It is typically used for 10–7–10 and 10–6–10 bit conversions.

9.3.3.4.7 ISS ISP IPIPEIF Dark-Frame Subtraction Functionality

Figure 9-51 shows the ISS ISP IPIPEIF dark-frame subtraction subblock.

Figure 9-51. ISS ISP IPIPEIF Dark-Frame Subtraction Subblock

camss-033

The dark-frame subtract (DFS) function is used to remove fixed pattern baseline noise from the sensor for a high-quality still image capture use case, where there is a mechanical shutter. Typically, the ISIF module previously writes a dark frame (frame captured when the shutter is closed) to SDRAM using 8 bits of linear data packed into 2 pixels per 16 bits.

In this mode, RAW data from the ISIF and SDRAM is used. Data can also be read from SDRAM with the [IPIPEIF_CFG1\[9:8\] UNPACK](#) bit field set to 1. Each pixel read from SDRAM is subtracted from each pixel sent from the VP or ISIF.

The mux at the input of the dark-frame subtraction subblock is implicitly controlled by the selection of the [IPIPEIF_CFG1\[15:14\] INPSRC1](#) and [IPIPEIF_CFG1\[3:2\] INPSRC2](#) bit fields:

- When [IPIPEIF_CFG1\[15:14\] INPSRC1](#) = 0x2, the selected input ports are VP and BL. Therefore, the dark frame operation can be:
 - Dark frame = VP – BL
 - Dark frame = BL – VP
- When [IPIPEIF_CFG1\[3:2\] INPSRC2](#) = 0x2, the selected input ports are ISIF and BL. Therefore, the dark frame operation can be:
 - Dark frame = ISIF – BL
 - Dark frame = BL – ISIF

The output of the DFS operation is 12 bits wide (U12Q0). There must be adequate SDRAM bandwidth if this feature is enabled. If the data fetched from memory arrives late, an underflow bit (IPIPEIF_DTUF) must be triggered to know it.

When SDRAM data underflow occurs, the data from SDRAM is coming in at a lower rate than the rate at which it is being read/requested by the IPIPEIF. In DFS operation mode, IPIPEIF reads data from both SDRAM and the VP/ISIF. To ensure not corrupting subsequent data processing downstream in the case of SDRAM data underflow, the IPIPEIF stalls the input data, storing remaining sensor data into an internal FIFO (16-deep), and then stops sending new data downstream. The IPIPEIF recommences DFS processing when data from SDRAM becomes available, by using the pixel data from the FIFO and that from SDRAM for processing. To avoid an overflow of the internal FIFO, the IPIPEIF deasserts the stall

only when the number of FIFO slots indicated by the `IPIPEIF_DTUDF[5:2]` FIFOWMRKLVL register bit field are free. A safe number of free locations can be configured taking into consideration the pixel clock frequency with respect to that of the functional clock, as the pixel clock speed is allowed to vary up to the functional clock speed. When the pixel clock and functional clock are equal, the stall deassertion can be programmed to occur when the 16-deep FIFO is empty.

9.3.3.4.7.1 ISS ISP IPIPEIF Defect Pixel Correction

NOTE: For DPC memory access locations, see [Section 9.3.3.11, ISS ISP Memory Mapping](#).

A simple DPC can be applied to the ISIF or VP input data path and SDRAM input data path, respectively. This DPC algorithm is intended to correct hot pixels during RAW dark frame acquisition or dark frame readout from SDRAM before dark frame subtraction.

The following code describes DPC algorithm:

```
If (image(n) < TH) || ((image(-2) < TH)&&(image(n+2)>TH)
    image(n) = image(n)
Else if image(-2) > TH
    image(n) = image(n+2)
Else if image(n+2) > TH
    image(n) = image(-2)
Else
    image(n) = (image(-2)+ image(n+2))/2

// Where TH is equal to IPIPEIF_DPC1[11:0] TH for DPC1
// Where TH is equal to IPIPEIF_DPC2[11:0] TH for DPC2
```

The `IPIPEIF_DPC1[12]` ENA bit enables DPC for the VP/ISIF input path, and the `IPIPEIF_DPC2[12]` ENA bit enables DPC for the SDRAM input path. The algorithm requires a threshold value that is set by the `IPIPEIF_DPC1[11:0] TH` or `IPIPEIF_DPC2[11:0] TH` bit field that is a 12-bit unsigned value.

9.3.3.4.7.2 ISS ISP IPIPEIF DFS Subtraction Direction

The `IPIPEIF_CFG2[5]` DFSDIR bit selects how the DFS subtraction is performed.

- Set the `IPIPEIF_CFG2[5]` DFSDIR bit to 0 when the RAW data is coming from the VP/ISIF and the dark frame is stored in SDRAM.
- Set the `IPIPEIF_CFG2[5]` DFSDIR bit to 1 when the RAW data is coming from SDRAM and the dark frame is coming from the VP/ISIF.

After subtraction, a clip ensures that the value is not negative.

[Table 9-208](#) lists the different modes supported in DFS.

Table 9-208. ISS ISP IPIPEIF DFS Modes Supported

Description	DFDIR Value
DFS of 8-bit RAW image stored in SDRAM from image from VP	<code>IPIPEIF_CFG2[5]</code> DFSDIR = 0x0
DFS of 8-bit RAW image stored in SDRAM from image from ISIF	<code>IPIPEIF_CFG2[5]</code> DFSDIR = 0x0
DFS of 8-bit RAW image from VP from image read from SDRAM through the BL	<code>IPIPEIF_CFG2[5]</code> DFSDIR = 0x1

NOTE: DFS input depends on the settings of INPSRC1 and INPSRC2.

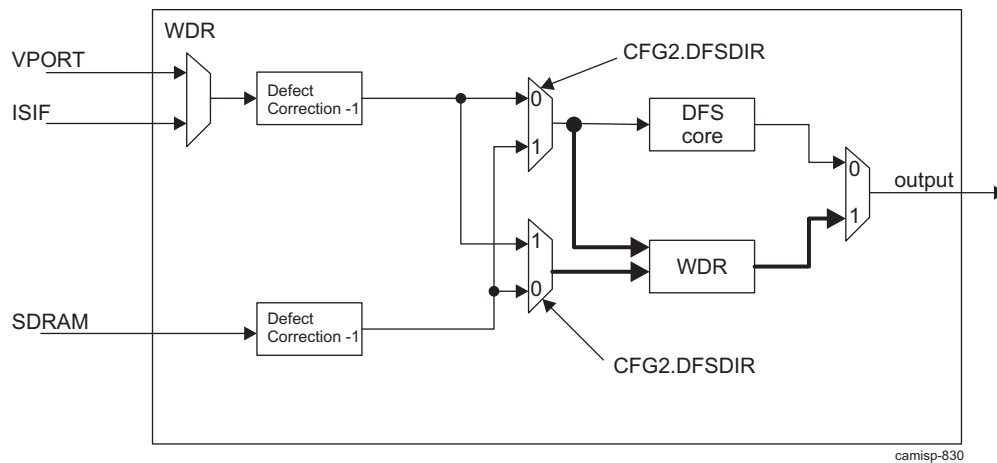

9.3.3.4.8 ISS ISP IPIPEIF Wide Dynamic Range WDR Merging Functionality

WDR Merging mode with VPORT/ISIF RAW Input with SDRAM Input (IPIPEIF_CFG1 .INPSRC1 =2 or IPIPEIF_CFG1 .INPSRC2 = 2, IPIPEIF_CFG4 .WDR=1)

9.3.3.4.8.1 ISS ISP IPIPEIF merging general description

In this mode, the input from VPORT/ISIF Port is merged with the input from SDRAM. The data flow is same as DFS mode, except the output is 16 bit. Also, the input streams were typically two 12bit pixel streams. All the other restrictions and notes about data flow in DFS process are also applied to WDR more.

Figure 9-52. ISS ISP IPIPEIF DFS/WDR sub block (WDR Mode)

9.3.3.4.9 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for IPIPE Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled (IPIPEIF_CFG1[1] DECIM), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can be enabled by setting the IPIPEIF_CFG1[7] AVGFILT bit. It operates on every other pixel (same color) in RAW Bayer input or every Y component in YCbCr data in the following equation:

$$\text{output} = (\text{input}[i - 1] + 2 \times \text{input}[i] + \text{input}[i + 1]) \gg 2$$

The averaging filter operates on every other pixel (same color) in RAW Bayer input or YUV data.

If the data is YUV4:2:2, the option to average and decimate is given under the conditions listed in Table 9-209.

Table 9-209. ISS ISP IPIPEIF Averaging Filter Conditions for YUV4:2:2 Data

IPIPEIF_CFG1[3:2] INPSRC2	IPIPEIF_CFG2[3] YUV16	Comments
0	1	YUV4:2:2 data is coming from the ISIF module. Averager and decimation is possible on the data path to the IPIPE module.
1	1	YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module.
3		YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module.
Other value	Other value	For YUV4:2:2 data, averager and decimation is not possible on the data path to the IPIPE module.

The averager implements a (1, 2, 1) FIR filter on Luma and Chroma. The following registers have a part in the behavior of the YUV data averaging and decimation:

- [IPIPEIF_INIRSZ\[12:0\]](#) INIRSZ
- [IPIPEIF_CFG1\[7\]](#) AVGFILT
- [IPIPEIF_CFG1\[1\]](#) DECIM

9.3.3.4.10 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for IPIPE Data Path

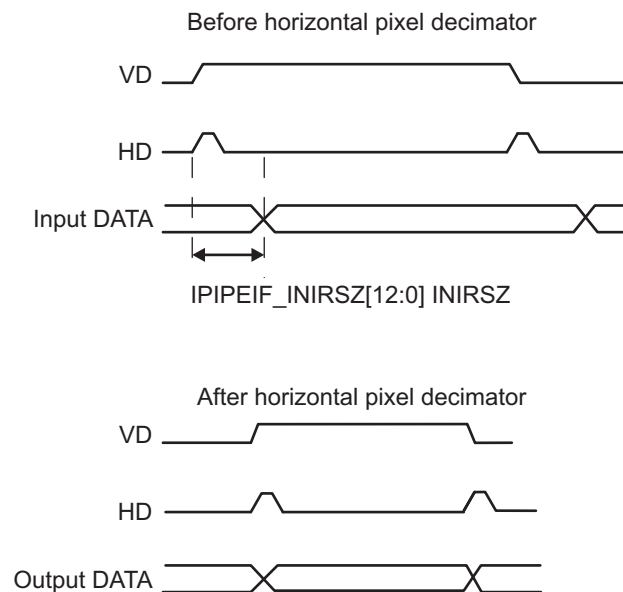

The IPIPE input is limited to 2816 pixels per horizontal line due to restrictions in the line memory width in the IPIPE.

To process image sensor resolutions with more than 2816 pixels per line with no resolution loss, vertical frame division mode (FDM) must be used; that is, the image must be divided into vertical chunks of less than 2816 pixels, and each chunk must be processed sequentially by the ISP. FDM is memory-to-memory processing and is not supported on the fly.

Alternatively, if a loss in resolution is acceptable, the line width decimator (the [IPIPEIF_CFG1\[1\]](#) DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 2816 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the [IPIPEIF_RSZ\[6:0\]](#) RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled ([IPIPEIF_INIRSZ\[13\]](#) ALNSYNC = 0x1), the [IPIPEIF_INIRSZ\[12:0\]](#) INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator, as shown in [Figure 9-53](#).

Figure 9-53. ISS ISP IPIPEIF Resizer Offset Definition

camss-614

9.3.3.4.11 ISS ISP IPIPEIF RAW Data Gain for IPIPE Data Path

A gain factor ranging from 0.00195(1/512) to 1.99805(1023/512) is multiplied to the RAW output of the IPIPEIF. The gain is not applied if the input data is YCbCr. The gain constant is set in the [IPIPEIF_GAIN\[9:0\]](#) GAIN bit field using U10Q9 format.

The output value is clipped after gain control through the value of the [IPIPEIF_OCLIP\[11:0\]](#) OCLIP bit field.

9.3.3.4.12 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for H3A Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled (the [IPIPEIF_RSZ3A\[9\]](#) DECIM bit), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can also be used to reduce noise before H3A statistics generation. It operates on every other pixel (the same color) in a RAW Bayer input or every Y component in YCbCr data. The averaging filter can be enabled by setting the [IPIPEIF_RSZ3A\[8\]](#) AVGFILT bit, and it operates with the following equation:

$$\text{output} = (\text{input}[i - 1] + 2 \times \text{input}[i] + \text{input}[i + 1]) \gg 2$$

9.3.3.4.13 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for H3A Data Path

The H3A input is limited to 3008 pixels per horizontal line due to restrictions in the line memory width in the H3A.

To process image-sensor resolutions with more than 3008 pixels per line with no resolution loss, vertical FDM must be used; that is, the image must be divided into vertical chunks of less than 3008 pixels, and each chunk must be processed sequentially by the ISP. FDM is memory-to-memory processing and is not supported on the fly.

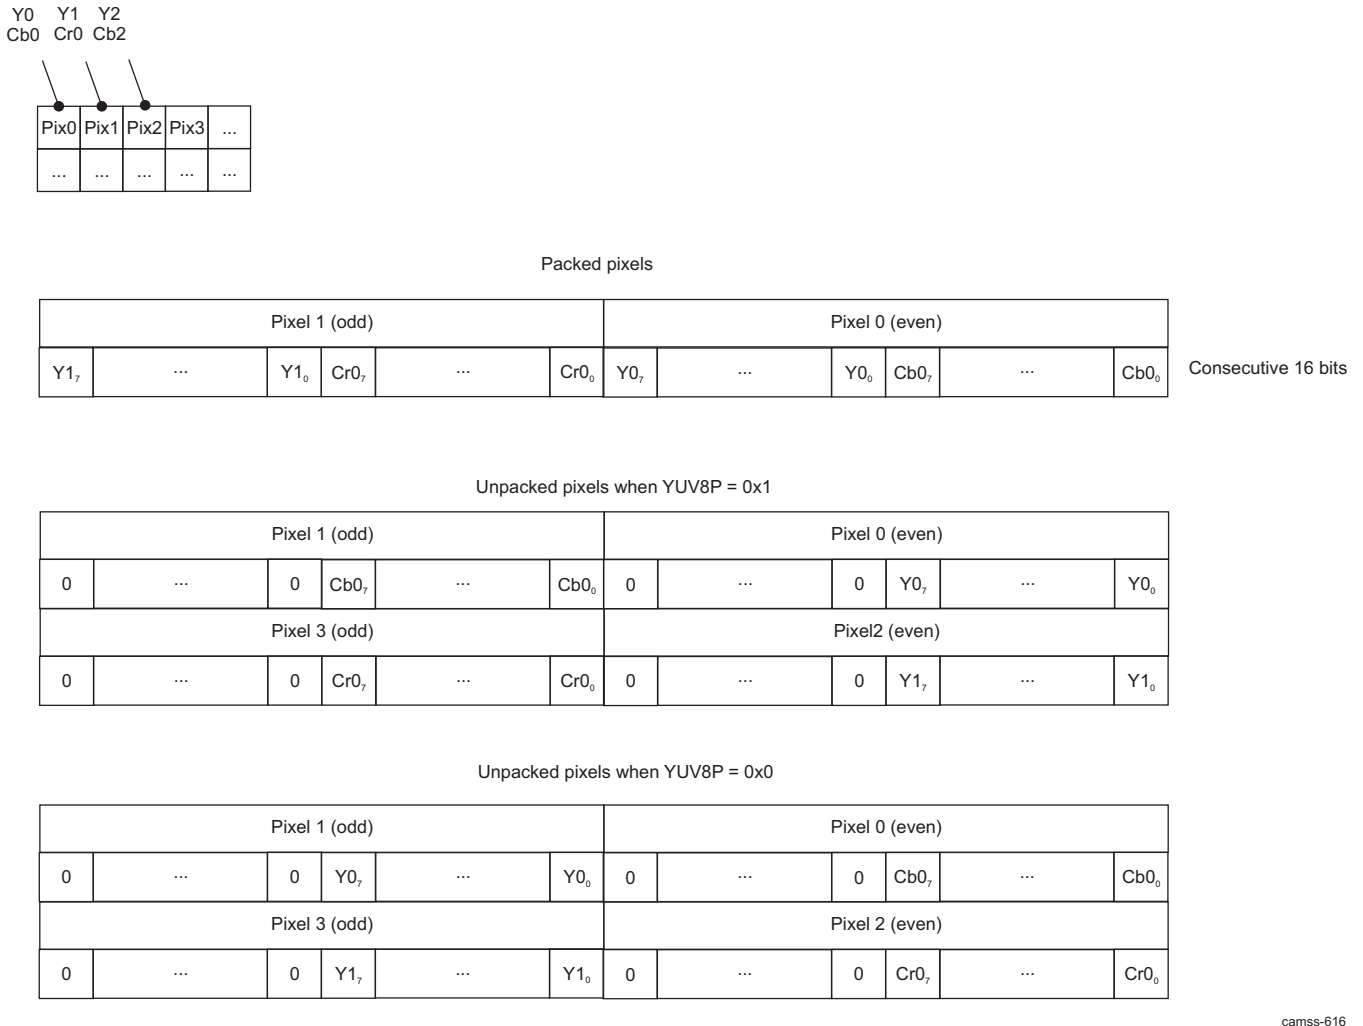

Alternatively, if loss of resolution is acceptable, the line width decimator (the [IPIPEIF_RSZ3A\[9\]](#) DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 3008 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the [IPIPEIF_RSZ3A\[6:0\]](#) RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled ([IPIPEIF_INIRSZ3A\[13\]](#) ALNSYNC = 0x1), the [IPIPEIF_INIRSZ3A\[12:0\]](#) INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator (see [Figure 9-53](#)).

9.3.3.4.14 ISS ISP IPIPEIF YUV4:2:2 8-bit Packed Data Input Coming From ISIF Module

This section applies when data coming from the ISIF is 8 bits ([IPIPEIF_CFG2\[6\]](#) YUV8 = 0x1). When [IPIPEIF_CFG1\[3:2\]](#) INPSRC2 = 0 and [IPIPEIF_CFG2\[3\]](#) YUV16 = 1, the 8-bit YUV data are transformed into 16-bit YUV data. The way the data are unpacked from 8 bits to 16 bits is controlled by the [IPIPEIF_CFG2\[7\]](#) YUV8P bit. See [Figure 9-54](#).

Figure 9-54. ISS ISP IPIPEIF YUV8P Settings

9.3.3.4.15 ISS ISP IPIPEIF YUV4:2:0 Data Input for Memory-to-Memory Resize Operations

The ISP RSZ module can resize YUV4:2:0 data. The YUV4:2:0 data can come from the memory (through BL) or from the VP through the receiver modules, which reads data from SDRAM and pushes it to the IPIPEIF module VP. The possible data paths are:

- SDRAM → IPIPEIF (BL) → RESIZER → SDRAM
- SDRAM → CAL_B → IPIPEIF (VP) → RESIZER → SDRAM
- SDRAM → IPIPEIF (BL) → IPIPEIF → RESIZER → SDRAM
- SDRAM → CAL_B → IPIPEIF (BL) → IPIPEIF → RESIZER → SDRAM

When the data comes from BL, the IPIPEIF module must be set up to process the Luma data first, and then the Chroma data.

- For 420Y (first pass):
 - IPIPEIF_CFG1[15:14] INPSRC1 = 0x1 (SDRAM data input)
 - IPIPEIF_CFG1[3:2] INPSRC2 = 0x1 (SDRAM data input)
 - IPIPEIF_CFG1[13:11] DATASFT = 0x0 (no data shift)
 - IPIPEIF_CFG1[9:8] UNPACK = 0x1 (data packed on 8 bits)
 - IPIPEIF_CFG2[3] YUV16 = 0x1 (data_input[7:0] = 0 and data_input[15:8] = valid)
- For 420C (second pass):

- [IPIPEIF_CFG1\[15:14\]](#) INPSRC1 = 0x1 (SDRAM data input)
- [IPIPEIF_CFG1\[3:2\]](#) INPSRC2 = 0x1 (SDRAM data input)
- [IPIPEIF_CFG1\[13:11\]](#) DATASFT = 0x0 (no data shift)
- [IPIPEIF_CFG1\[9:8\]](#) UNPACK = 0x1 (data packed on 8 bits)
- [IPIPEIF_CFG2\[3\]](#) YUV16 = 0x0 (data_input[7:0] = valid and data_input[15:8] = 0)

9.3.3.4.16 ISS ISP IPIPEIF Module Events and Status Checking

The IPIPEIF module generates an IPIPEIF event through the IPIPEIF_IRQ interrupt at the end of each frame. This interrupt is set through the [ISP5_IRQENABLE_SET_i\[9\]](#) IPIPEIF_IRQ bit. The input interrupt source generation is selected through the [IPIPEIF_CFG2\[0\]](#) INTSW bit in a certain configuration. The following pseudo code describes INTSW.

```

if (IPIPEIF_CFG2[0] INTSW==0) // Interrupt source from VP
  if (IPIPEIF_CFG1[15:14] INPSRC1==1,2 or 3)
    if (CFG1.ONESHOT==1) // In one shot mode
      Interrupt happens at the end of frame
    else // In continuous mode
      Interrupt is the start position of VD which is generated by IPIPEIF timing generator
    else // IPIPEIF_CFG1[15:14] INPSRC1==0, data is from VP
      Interrupt is the start position of VD from VP

else // Interrupt source from ISIF: IPIPEIF_CFG2[0] INTSW==1
  if (IPIPEIF_CFG1[3:2] INPSRC2==1,2 or 3)
    if (CFG1.ONESHOT==1) // In one shot mode
      Interrupt happens at the end of frame
    else
      Interrupt is the start position of VD which is generated by IPIPEIF timing generator
    else // IPIPEIF_CFG1[3:2] INPSRC2==0, data is from ISIF
      Interrupt is the start position of VD from ISIF
  
```

In addition to this interrupt, the host must check the IPIPEIF_DTUF status flag of the [ISP5_IRQSTATUS_RAW2_i\[1\]](#) IPIPEIF_UDF bit (if this is enabled and mapped to the ISP IRQ lines) to see if an underflow occurred.

If IPIPEIF reads image data from memory, IPIPEIF stalls data output by masking the clock at underflow. When the next data is available at the input side, IPIPEIF restarts sending data. Underflow does not occur in this operation.

In DFS operation (see [Section 9.3.3.4.7, ISS ISP IPIPEIF Dark-Frame Subtraction Functionality](#) for more information), if the data read from memory are not available before they are required, the behavior of IPIPEIF is as follows:

- If image data is being received through a receiver module, then IPIPEIF raises IPIPEIF_STALL signal to stall CAL_B. The [IPIPEIF_DTUDF\[1\]](#) ENM2MSTALL bit controls whether the IPIPEIF raises IPIPEIF_STALL signal at underflow event or not.

9.3.3.5 ISS ISP IPIPE Functional Description

9.3.3.5.1 ISS ISP IPIPE Overview

- The input interface extracts the valid region from the Bayer RAW data:
 - Up to 12-bit input pixel resolution in Bayer format
 - 16bit (8bit Y + 8bit U or V) in YUV format
 - Requires at least 8 pixels for horizontal blanking and four lines for vertical blanking. In one-shot mode; 16 blanking lines after processing area are required.
 - The maximum horizontal and vertical offset of IPIPE processing area from synchronous signal is 65534.
 - Supports RGB Bayer pattern for input
- The DPC module fixes defect pixels using two methods: LUT-based and on-the-fly adaptive.

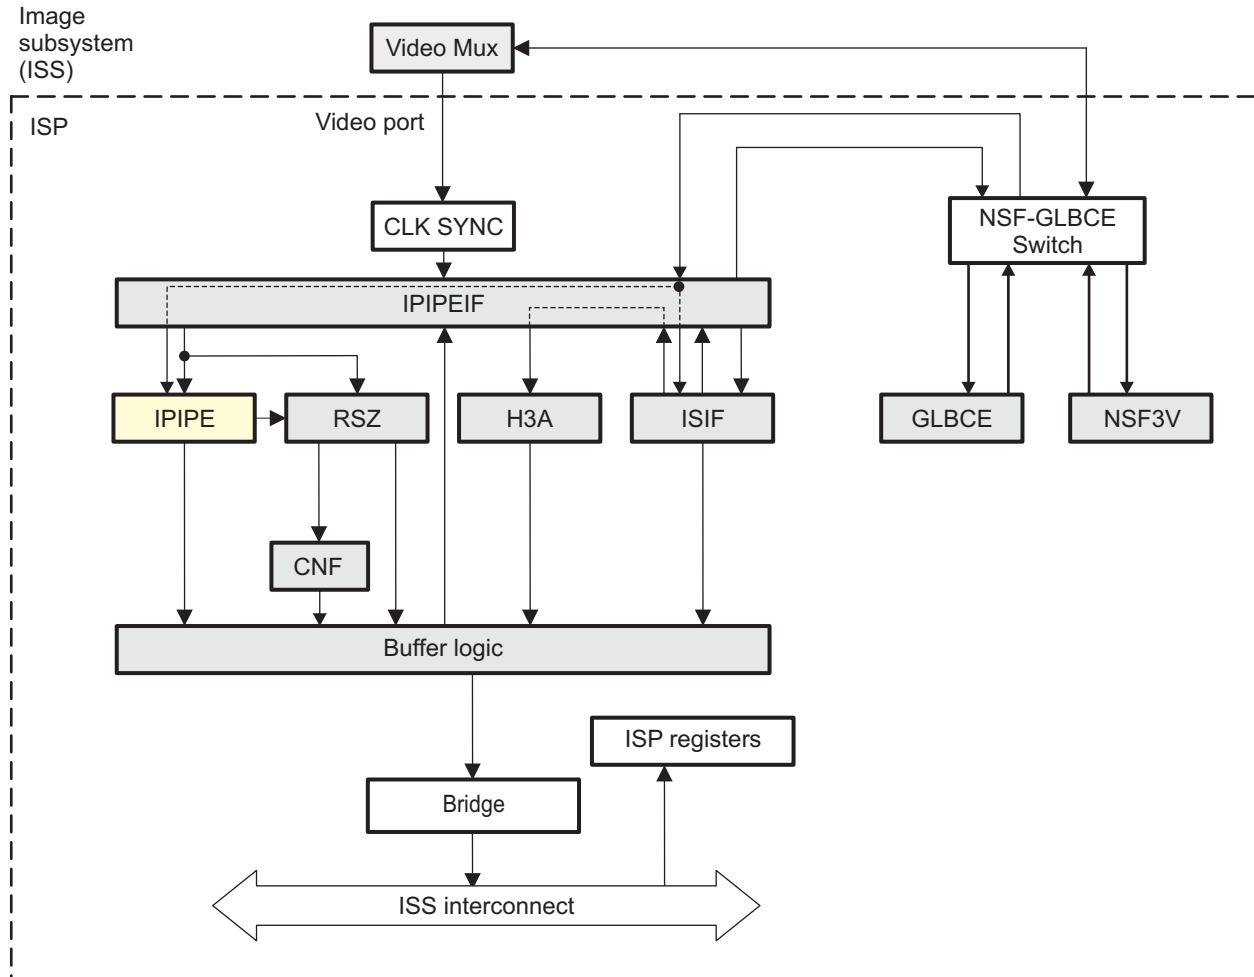

- DPC works with NSF3V module
- The 2D noise-filter module reduces noise in RAW data.
- The green-imbalance-correction (GIC) module reduces Gb/Gr difference to remove line crawl noise.
- The white balance module applies offset and gain adjustments to each color.
- The color filter array (CFA) interpolation module implements CFA interpolation. The output from the CFA interpolation module is RGB-4:4:4 formatted data. CFA also reduces aliasing caused by undersampling by digital anti-aliasing (DAA).
- The RGB2RGB blending module applies a 3×3 matrix transform to the RGB data generated by the CFA interpolation module.
- The gamma correction module independently applies gamma correction to each RGB component. Gamma is implemented using a piece-wise linear interpolation approach with a 512-entry LUT for each color.
- The second RGB2RGB blending module applies a 3×3 matrix transform to the RGB data after gamma correction.
- 3D-LUT converts RGB data to RGB data using $9 \times 9 \times 9$ table and tetrahedral interpolation.
- The RGB2YCbCr conversion module applies 3×3 matrix transformation to the RGB data to convert it to YCbCr data. This module also implements offset. The global brightness and contrast enhancement module fixes brightness and contrast tone.
- The 4:2:2 conversion module applies the Chroma low-pass filter and downsampling to Cb and Cr to convert 4:4:4 data to 4:2:2 data.
- The 2D edge-enhancer module improves image clarity with a Luma nonlinear filter.
- The Chroma artifact reduction module reduces color artifacts using gain control and a 2D median filter.
- The output interface module transfers data from IPIPE to SDRAM in the form of one YCbCr (4:2:2 or 4:2:0), RGB (32/16 bits), or Bayer data.
- The histogram function can record histograms of up to four distinct areas into up to 256 bins.
- The boxcar function makes 1/8 or 1/16 size (1/64 or 1/256 in area) images.
- The boundary signal calculator (BSC) makes vectors of row and column summations.
- Convert YUV422 to full color RGB

IPIPE has four processing paths:

- Case 1: IPIPE reads CCD RAW data and applies all IPIPE functions and stores the YCbCr (or RGB) data to SDRAM.
- Case 2: IPIPE reads CCD RAW data and stores the Bayer data after white balance to SDRAM.
- Case 3: IPIPE reads YCbCr-4:2:2 data and applies edge enhance, Chroma suppression, and resize to output YCbCr data to SDRAM.
- Case 4: IPIPE reads YCbCr-4:2:0 data and applies resize to output YCbCr data to SDRAM.
- Enhanced YUV input support.
- Color conversion, tone-curve mapping, 3D-LUT, GBCE, Histogram, BSC are supported on YUV input.

[Figure 9-55](#) shows the connections from the IPIPE module to other submodules of the ISP.

Figure 9-55. ISS ISP IPIPE High-Level Diagram

camisp-003d

9.3.3.5.2 ISS ISP IPIPE Top-Level Block Diagram

The IPIPE is a programmable hardware image-processing module that generates image data in YCbCr-4:2:2 or YCbCr-4:2:0 format from RAW CCD/CMOS data. The IPIPE module supports output of Bayer data.

The IPIPE module supports RAW data in Bayer format, as shown in Figure 9-56. Other RGB formats or complementary color formats are not supported.

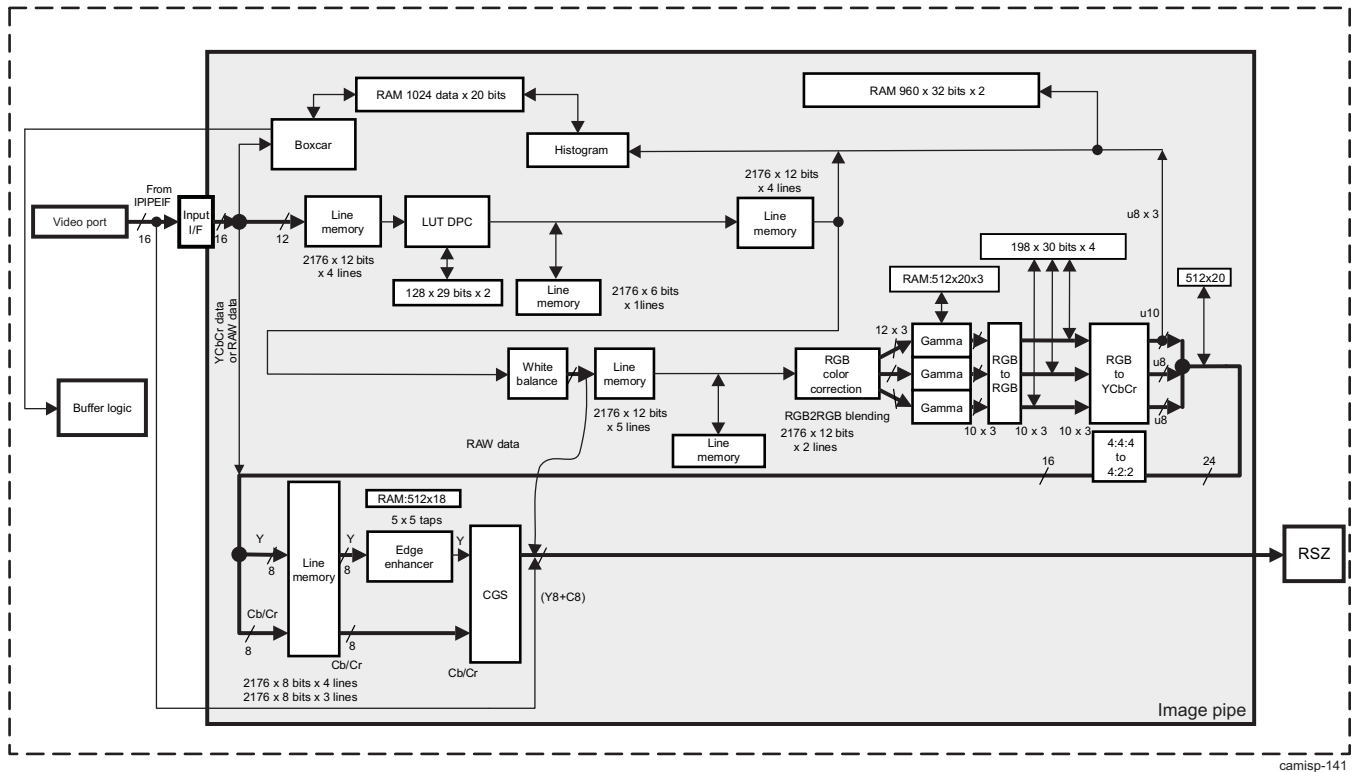

Figure 9-56. ISS ISP IPIPE Supported CFA Format

camisp-142

As shown in Figure 9-57, many internal modules are used to process Bayer data into YCbCr data.

Figure 9-57. ISS ISP IPIPE Module Block Diagram

camisp-141

9.3.3.5.3 ISS ISP IPIPE Input Interface

The IPIPE module receives 16-bit input data through the IPIPEIF module or from the NSF-GLBCE switch, which can be 12-bit RAW image data or 16-bit YCbCr data. The IPIPE module can work with up to 2816 pixels in each horizontal line, except in RAW pass-through mode. If the image width is larger than 2816, the image must be scaled down at the IPIPEIF module level. Otherwise, the input image must be split into several blocks.

The input image is accommodated with h-sync and v-sync signals (HD and VD). The cycles between one HD to the next HD must be 64 pclk or bigger.

If the input data is YCbCr, all there are three paths

- YUV422_MODE: All RGB processing modules are skipped, and only Edge Enhancer, Chroma Suppression, and Resizer are applied to the input data
- YUVtoRGB_MODE: YUV422 is converted to full color RGB, and all processes after RGB2RGB1 are applied. Also, histogram and BSC are measured.
- YUV444_MODE: YUV422 is up-sampled to YUV444, and all processes after GBCE are processed. Also BSC and Histogram are measured.

In RAW pass-through mode, images up to 8190 pixels per line can be processed. In RAW pass-through mode, the input data is written out directly to SDRAM.

The IPIPE module is enabled through the `IPIPE_SRC_EN[0]` EN bit.

The IPIPEIF module must be selected as the IPIPE module source with the `IPIPE_SRC_MODE[1]` WRT bit set to 1 from the input port of the IPIPEIF. This is required to enable and transfer data properly from the interface to the IPIPE.

The IPIPE module has two processing modes, which can be selected through the `IPIPE_SRC_MODE[0]` OST bit:

- One-shot mode: `IPIPE_SRC_MODE[0]` OST = 0x1

- Free-run mode: `IPIPE_SRC_MODE[0]` OST = 0x0

The input and output formats are selected in the `IPIPE_SRC_FMT[1:0]` FMT bit field (see Table 9-210).

Table 9-210. ISS ISP IPIPE Input and Output Selections

<code>IPIPE_SRC_FMT[1:0]</code> FMT	IPIPE Module Input	IPIPE Module Output
0x0	RAW Bayer	YCbCr or RGB
0x1	RAW Bayer	RAW Bayer
0x2	RAW Bayer	Disabled
0x3	YCbCr 16 bits	YCbCr

The 16-bit data input to the IPIPE module is in the formats (YCbCr-8bit is not allowed) shown in Figure 9-58.

Figure 9-58. ISS ISP IPIPE Module Input Format

IPIPE input	RAW	LOW	LOW	LOW	LOW	RAW11	RAW10	RAW9	RAW8	RAW7	RAW6	RAW5	RAW4	RAW3	RAW2	RAW1	RAW0
	YCbCr 16b	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Cb/Cr7	Cb/Cr6	Cb/Cr5	Cb/Cr4	Cb/Cr3	Cb/Cr2	Cb/Cr1	Cb/Cr0
Y 8bit	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	LOW	LOW	LOW	LOW	LOW	LOW	LOW	LOW	
CbCr 8bit	LOW	LOW	LOW	LOW	LOW	LOW	LOW	LOW	Cb/Cr7	Cb/Cr6	Cb/Cr5	Cb/Cr4	Cb/Cr3	Cb/Cr2	Cb/Cr1	Cb/Cr0	

camisp-143

The window to process can be defined by its vertical and horizontal start position (`IPIPE_SRC_VPS` and `IPIPE_SRC_HPS`, respectively) and vertical and horizontal size (`IPIPE_SRC_VSZ` and `IPIPE_SRC_HSZ`, respectively). Figure 9-59 shows the window settings for processing.

Figure 9-59. ISS ISP IPIPE Module Processing Window Settings

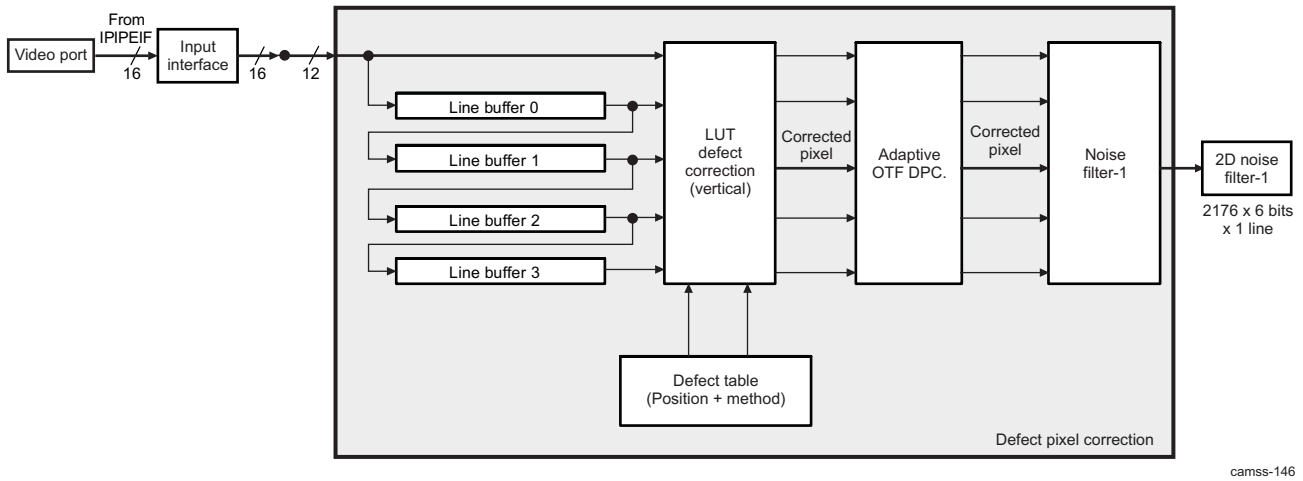

camss-639

9.3.3.5.4 ISS ISP IPIPE Defect Pixel Correction

NOTE: LUT DPC and OTF DPC can work with NSF3V using DPC port.

The DPC module corrects defect pixels using two methods: LUT-based method (LUT DPC) and on-the-fly adaptive method (OTF DPC). Figure 9-60 shows defect pixel correction.

Figure 9-60. ISS ISP IPIPE Defect Pixel Correction

camss-146

9.3.3.5.4.1 ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

LUT DPC is the first stage of the IPIPE image-processing pipeline. The LUT DPC module corrects defects in input data. It supports up to a 256-defect point table. However, the table can be renewed as required during image processing. Therefore, the maximum amount of defect information is limited only by system-level performance.

The module uses two sets of 128 × 29 memories to hold defect information. The table contains the information of horizontal position (13 bits), vertical position (13 bits), and correction method (3 bits), as shown in Table 9-211. The LUT DPC is enabled through the `IPIPE_DPC_LUT_EN[0]` EN bit.

Table 9-211. ISS ISP IPIPE Defect Information Packing

Correction Method	Vertical Position	Horizontal Position
28...26	25...13	12...0

The information must be listed from left to right and from the top to bottom. The first position in the defect information table and the number of defects that are used can be specified. The address of the table must be programmed in the `IPIPE_DPC_LUT_ADR[9:0]` ADR bit field. Thus, the address of the first valid data is stated.

The LUT type can be:

- With a finite number of entries:
 - `IPIPE_DPC_LUT_SEL[1]` TBL = 0x0
 - The size of the LUT is set in the `IPIPE_DPC_LUT_SIZ[9:0]` SIZ bit field.
- With an infinite number of entries:
 - `IPIPE_DPC_LUT_SEL[1]` TBL = 0x1

The correction methods, set in Table 9-211, are described in Table 9-212.

Table 9-212. ISS ISP IPIPE Correction Method Description

Correction Method	d0 =	Comment
0	Black or white dot	Replace with a black (or white) dot to force OTF-DPC to work on the pixel. White or black dot replacement can be selected through the <code>IPIPE_DPC_LUT_SEL[0]</code> DOT field.
1	d4	Copy from left
2	d5	Copy from right

Table 9-212. ISS ISP IPIPE Correction Method Description (continued)

Correction Method	d0 =	Comment
3	$(d4 + d5)/2$	Horizontal interpolation
4	$(d2 + d7)/2$	Vertical interpolation
5	d2	Copy from top
6	d7	Copy from bottom
7	$(d2 + d4 + d5 + d7)/2$	2D interpolation

The pixels in the defect correction algorithm are numbered as shown in [Figure 9-61](#).

Figure 9-61. ISS ISP IPIPE Pixel Numbering in Defect Correction Algorithm

The pixels at the edges are mirrored as way described in [Figure 9-62](#). The figure shows the typical correction by overwriting far-edge pixels and mirroring them with other edge pixels. The example shows how by using a noise filter the correct-by-definition pixels are copied over bad pixels.

Figure 9-62. ISS ISP IPIPE Mirroring in Defect Correction and Noise Filter

9.3.3.5.5 ISS ISP IPIPE DPC Interface

DPC is able to work with NSF3V module. In that case, the data comes from DPC input port and goes out from DPC output port. When DPC is working with NSF3V, DPC and NF-1 function are skipped inside IPIPE. In other words, DPC in NSF3V and DPC+NF-1 in IPIPE are mutually exclusive.

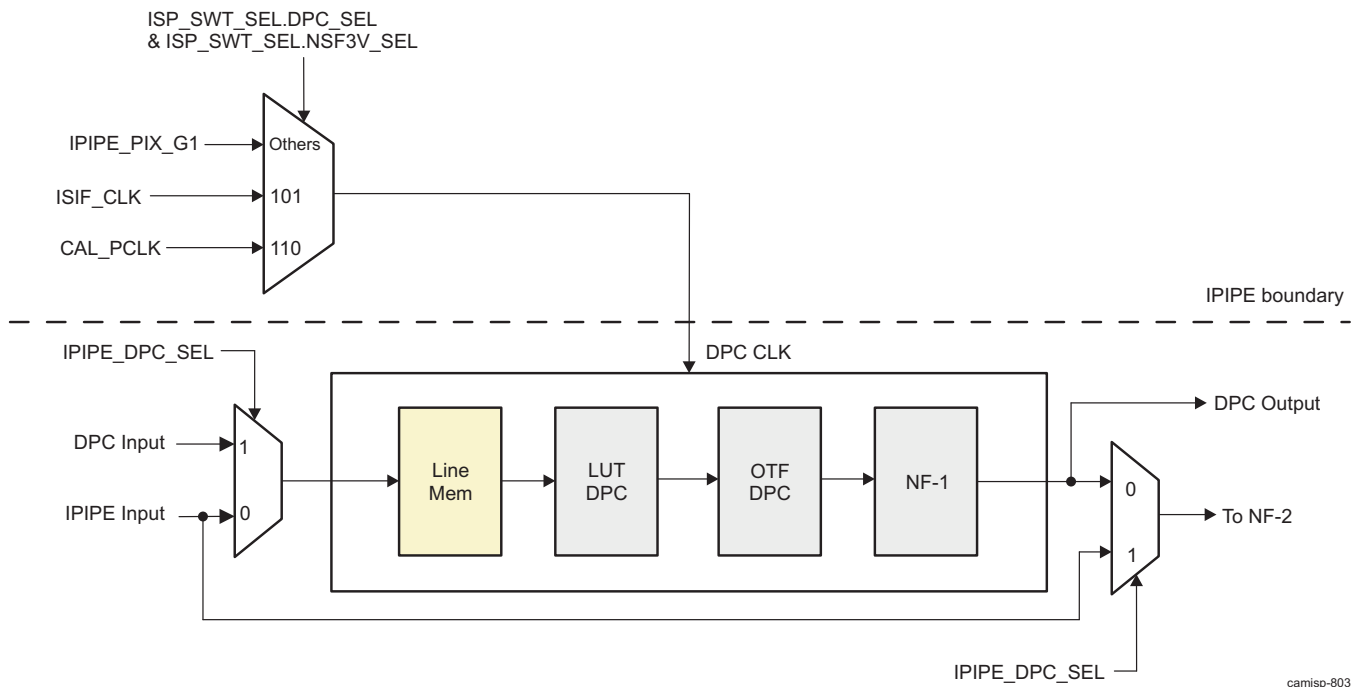

Also, it must be noted that the clock to DPC/NF-1 is driven by DPC_CLK instead of by pixel clock (PCLK) directly. If DPC works with the rest of IPIPE, DPC_CLK is exactly the same as PCLK. If DPC works with NSF3V, and if NSF3V works with ISP, DPC_CLK is same as ISIF_CLK. If DPC works with NSF3V, and if NSF3V works with CAL, DPC_CLK is same as CAL_PCLK. The DPC_CLK is generated at ISS level accordingly (ISS_MAIN_FCLK).

In addition, the image width must be 32 pixels or more if DPC works before NSF3V.

Table 9-213. ISS ISP IPIPE DPC_CLK

DPC Use Case	DPC_CLK source	Description
IPIPE	PCLK	Conventional case. DPC works inside IPIPE.
ISP-NSF3V	ISIF_FCLK	DPC works with NSF3V, and NSF3V works inside ISP. DPC gets the pixels from ISIF, and sends them to NSF3V. The image width must be 32 pixel or more.
CAL-NSF3V	CAL_PCLK	DPC works with NSF3V, and NSF3V works with CAL. DPC gets the pixels from CAL interface, and sends them to NSF3V. The image width must be 32 pixel or more.

Figure 9-63. ISS ISP IPIPE Data flow of DPC Interface

The input from DPC-input port must comply with IPIPE's internal signal protocol.

There are several control signals beside 12-bit data signal (Table 6). These signals need to follow the IPIPE internal signal protocol. HD lasts for one clock. VD, VWE, and VWI can only change on HD signal. EN is asserted on the next clock of HD, and keeps high status for n-clocks, where n is the width of the valid image area. The size of the valid width (the length of asserted EN signal) must be consistent throughout each frame. EN cannot be negated in the middle of the line

When DPC works before NSF3V, ID signal from NSF3V path is used instead of the ones generated by IPIPE.

When DPC is used with NSF3V, there are a couple of points that SW must obey. First, NF-1 must be turned off (*IPIPE_D2F_1ST_EN*. EN=0). Second, since turning off LUT-DPC/OTF-DPC/NF-1 all off force IPIPE to skip line buffers, SW must make sure the change of latency caused by turning on/off LUT-DPC/OTF-DPC does not affect the following processes. To avoid this point, SW can virtually disable the OTF-DPC by setting in a way that OTF does not filter any pixel. One example of such setting is as following.

- DPC_OTF_TYP [TYP] =0
- DPC_OTF_TYP [ALG] =0
- DPC_OTF_2_C_THR_x = 4095 (x=R, Gr, Gb, and B)

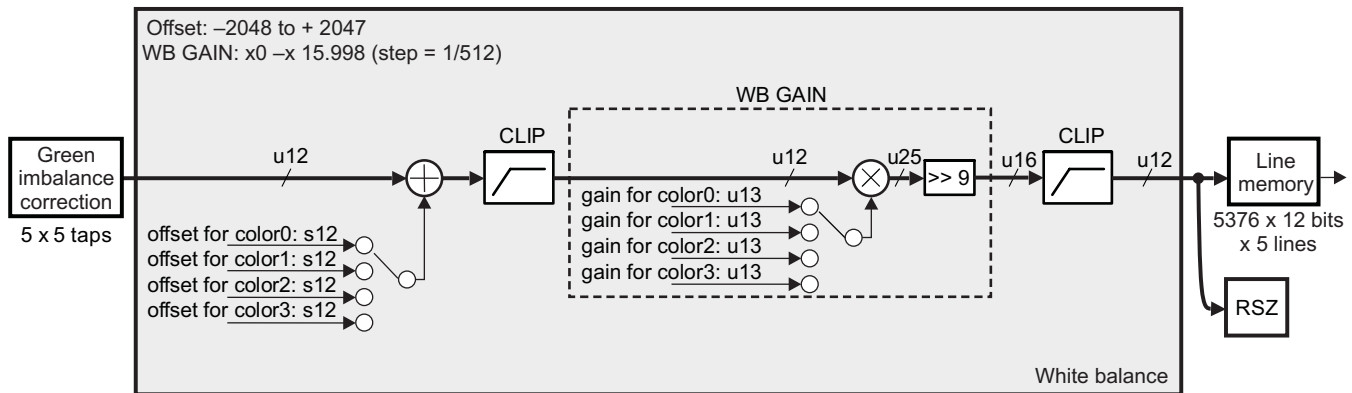

DPC_OTF_2_D_THR_x = 4095 (x=R, Gr, Gb, and B)

9.3.3.5.6 ISS ISP IPIPE White Balance

The white balance module executes white balance to each color component. White balance gain adjusts the ratio of each color existing in a CFA pattern. An offset can be applied before white balance correction (IPIPE_WB2_OFT_R, GR, Gb, or B registers).

Figure 9-64 is a block diagram of the white balance module. In the white balance gain adjuster, the RAW data is multiplied by a selected gain (IPIPE_WB2_WGN_R, Gr, Gb, or B registers) corresponding to the color. The white balance gain can be selected from four 13-bit values. Firmware can assign any combination of 4 pixels in horizontal and vertical directions. The precision of each gain is shown in the figure.

Figure 9-64. ISS ISP IPIPE White Balance

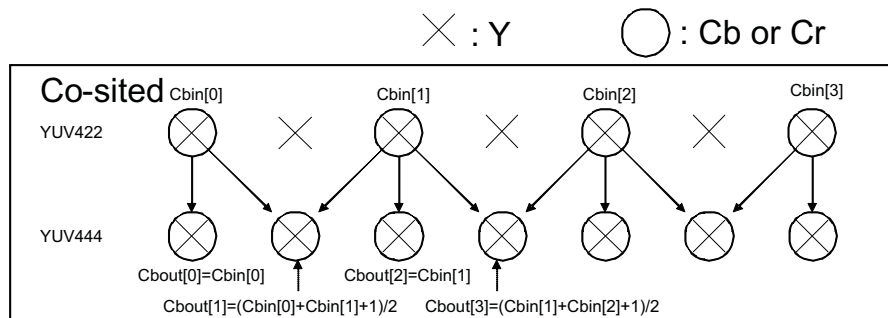

camisp-155

9.3.3.5.7 ISS ISP IPIPE YUV422to444

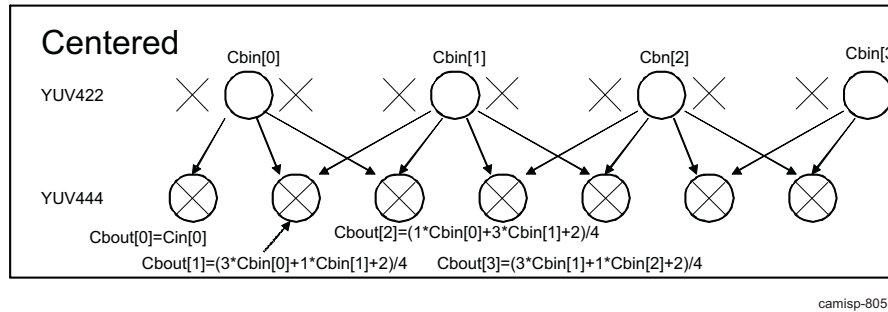

If the input is YUV422 and YUV444_MODE or YUVtoRGB_MODE is selected (SRC_FMT [FMT] =3, SRC_FMT [FMT2]=1 or 2), this module up-samples YUV422 to YUV444. (In YUVtoRGB_MODE, the next RGB2RGB module also converts YUV to RGB.) The module refers to SRC_FMT [FMT3] for the chroma sampling position. If the value is 0 (co-sited), the up-sampling is done in the way in Figure 9-65. If it is 1, it is done in the way Figure 9-66

Figure 9-65. ISS ISP IPIPE YUV422 to 444 in co-sited mode

camisp-804

Figure 9-66. ISS ISP IPIPE YUV422 to 444 in co-sited mode

9.3.3.5.8 ISS ISP IPIPE RGB2RGB Blending Module

The RGB2RGB blending module transforms the RGB data generated by the CFA interpolation module using a 3 x 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 9-67. Each gain range is from -8 to +7.996 with step 1/256 = 0.004, and is set in the IPIPE_RGB1_MUL_RR to IPIPE_RGB1_MUL_BB registers. The offset range for each component is from -4096 to 4095, and is set in the IPIPE_RGB1_OFT_OR to IPIPE_RGB1_OFT_OB registers.

Figure 9-67. ISS ISP IPIPE RGB2RGB Conversion Formula

$$\begin{matrix} R_out \\ G_out \\ B_out \end{matrix} = \begin{matrix} gain_RR & gain_GR & gain_BR \\ gain_RG & gain_GG & gain_BG \\ gain_RB & gain_GB & gain_BB \end{matrix} \begin{matrix} R_in \\ G_in \\ B_in \end{matrix} + \begin{matrix} offset_R \\ offset_G \\ offset_B \end{matrix}$$

camss-650

If the input is YUV422 and RGB mode is selected (SRC_FMT [FMT]=3, SRC_FMT [FMT2]=2), this module is used as YUV444toRGB conversion.

In case of YUV input, RGB are replaced by YCbCr

- R_in = (ClipS9(Y_in+Y_offset)) << 4
- G_in = (ClipS9(Cb_in+Cb_offset)) << 4
- B_in = (ClipS9(Cr_in+Cr_offset)) << 4
 - ClipS9(x)=(x<-256 ? -256 : ((x>255) ? 255 : x)
 - Y/Cb/Cr_Offset are s9 (-256 to +255)
- R_in/G_in/B_in are expanded to S13 to support these modes

One typical equation for YUVtoRGB conversion is the following, which converts JPEG YUV to RGB.

Figure 9-68. ISS ISP IPIPE equation for YUVtoRGB conversion

$$\begin{pmatrix} R \\ G \\ B \end{pmatrix} = \begin{pmatrix} 0.299 & 0.587 & 0.114 \\ -0.168736 & -0.331264 & 0.5 \\ 0.5 & -0.418688 & -0.081312 \end{pmatrix}^{-1} \begin{pmatrix} Y_{in} \\ Cbin - 128 \\ Crin - 128 \end{pmatrix}$$

camisp-806

The matrix corresponding to this equation is

Figure 9-69. ISS ISP IPIPE equation for YUVtoRGB conversion matrix

$$\begin{pmatrix} 256 & 0 & 359 \\ 256 & -88 & -183 \\ 0.5 & 454 & 0 \end{pmatrix}$$

camisp-807

9.3.3.5.9 ISS ISP IPIPE Gamma Correction Module

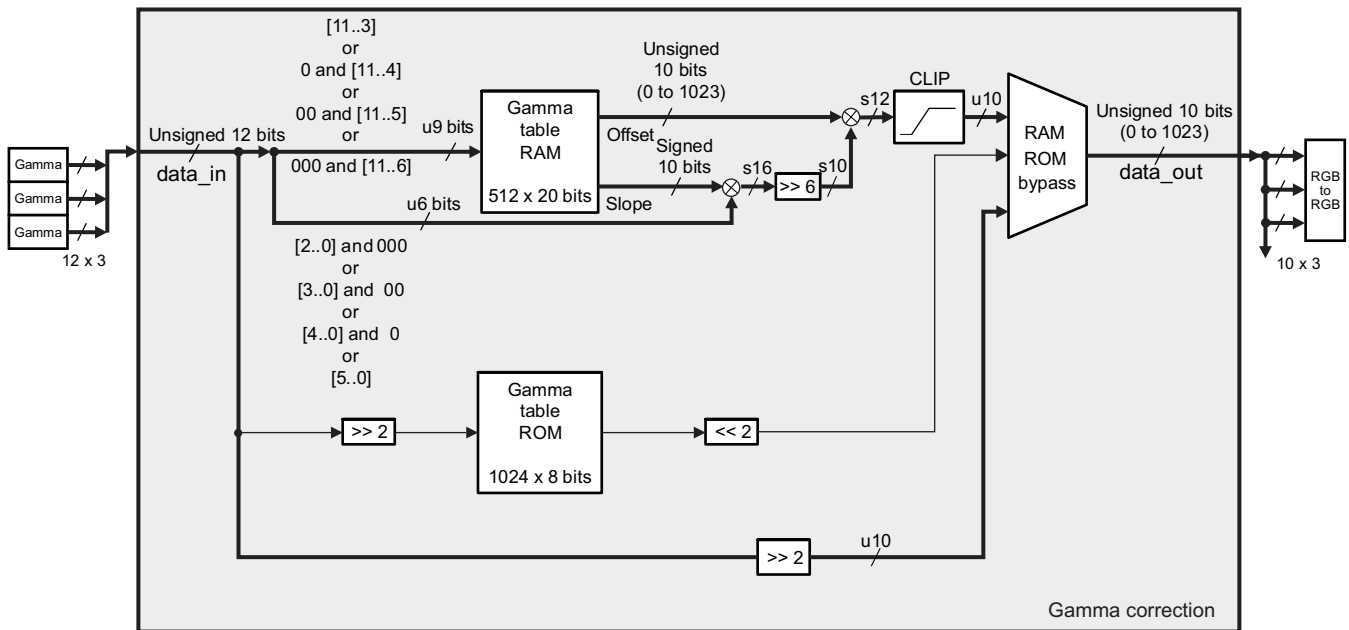

NOTE: For the memory access locations of the gamma correction module, see [Section 9.3.3.11, ISS ISP Memory Mapping](#).

The gamma correction module performs gamma correction independently for each color in the RGB color space by using a piece-wise linear interpolation. ROM tables and RAM tables are selectable through the `IPIPE_GMM_CFG[4]` TBL bit. Each ROM table and RAM table has 512 entries, and each entry accommodates a 10-bit offset and 10-bit slope. The range of slope value is from -512 to +511. The ROM table has 1024 entries and an output 8-bit value.

Figure 9-70 is a block diagram of the gamma correction module. It is composed of two tables and one selector. When the BYPASS bit is asserted, the input data is divided by 16 (the `IPIPE_GMM_CFG[0]` BYPR, `IPIPE_GMM_CFG[1]` BYPG, and `IPIPE_GMM_CFG[2]` BYPB bits).

Figure 9-71 shows an example of the gamma curve. Figure 9-72 shows offset and slope packing.

Figure 9-70. ISS ISP IPIPE Gamma Correction Module Block Diagram

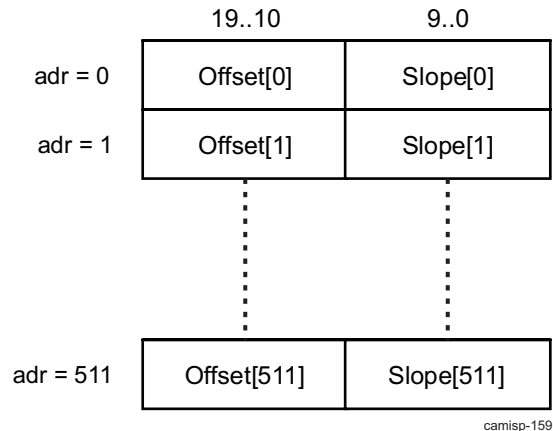

camisp-157

camss-158

Figure 9-72. ISS ISP IPIPE Gamma Table Offset and Slope Packing

9.3.3.5.10 ISS ISP IPIPE Second RGB2RGB Conversion Matrix

The second RGB2RGB blending module transforms the RGB data after gamma correction using the 3 × 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 9-73. Each gain range is from -4 to +3.996 with step 1/256 = 0.004 (s3.8), and is set in the IPIPE_RGB2_MUL_RR to IPIPE_RGB2_MUL_BB registers. The offset is -1024 to 1023 (s11), and is set in the IPIPE_RGB2_OFT_OR to IPIPE_RGB2_OFT_OB registers.

Figure 9-73. ISS ISP IPIPE RGB2RGB Second Conversion Formula

$$\begin{aligned}
 R_out &= gain_RR \cdot gain_GR \cdot gain_BR \cdot R_in + offset_R \\
 G_out &= gain_RG \cdot gain_GG \cdot gain_BG \cdot G_in + offset_G \\
 B_out &= gain_RB \cdot gain_GB \cdot gain_BB \cdot B_in + offset_B
 \end{aligned}$$

camss-650

9.3.3.5.11 ISS ISP IPIPE RGB2YCbCr Conversion Matrix

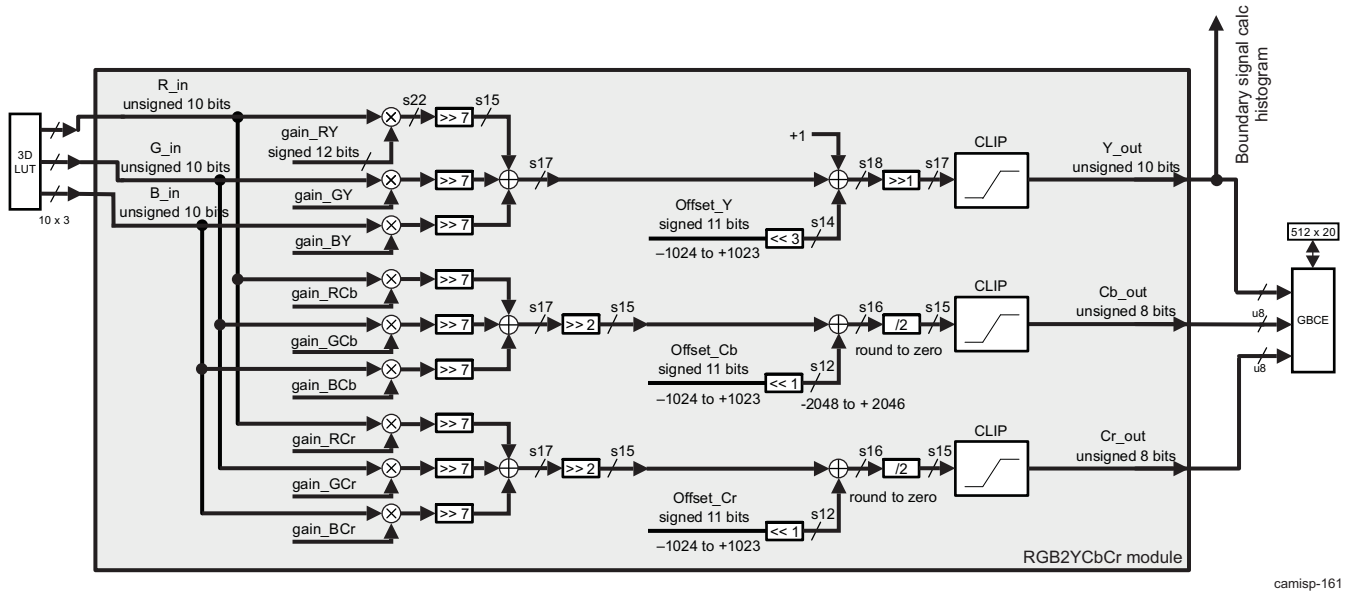

This module transforms the RGB data to YCbCr data format using a 3 × 3 matrix transformation in combination with an added offset. While transferring, the brightness control and contrast control can be adjusted using the IPIPE_YUV_ADJ[15:8] BRT and IPIPE_YUV_ADJ[15:8] CRT bit fields, respectively. Then, the transform is calculated using the formula shown in Figure 9-74. Each gain range is from -8 to +7.996 with step 1/256 = 0.004, configured in the IPIPE_YUV_MUL_RY to IPIPE_YUV_MUL_BCR registers. The offset is -1024 to +1023 for Y, Cb, and Cr, configured in the IPIPE_YUV_OFT_Y to IPIPE_YUV_OFT_CR registers. Figure 9-75 is the block diagram of the RGB to YCbCr blending module. The output is calculated by the equation.

Figure 9-74. ISS ISP IPIPE RGB2YCbCr Conversion Formula

$$\begin{aligned}
 Y_out &= gain_RY \cdot gain_GY \cdot gain_BY \cdot R_in + offset_Y \\
 Cb_out &= gain_RCb \cdot gain_GCb \cdot gain_BCb \cdot G_in + offset_Cb \\
 Cr_out &= gain_RCr \cdot gain_GCr \cdot gain_BCr \cdot B_in + offset_Cr
 \end{aligned}$$

camss-654

Figure 9-75. ISS ISP IPIPE RGB2YCbCr Module Block Diagram

camisp-161

9.3.3.5.12 ISS ISP IPIPE 4:2:2 Conversion Module

The 4:2:2 conversion module converts the image data to YCbCr-4:2:2 format by taking the average of every two Cb and Cr components. Y and Cb/Cr sampling point of spatial cosited or spatial centering are selectable using the IPIPE_YUV_PHS[0] POS bit. Horizontal 3 taps and 4- or 2-tap filters are used for spatial cosited and spatial centering, respectively. The module is enabled from the IPIPE_YUV_PHS[1] PLF bit.

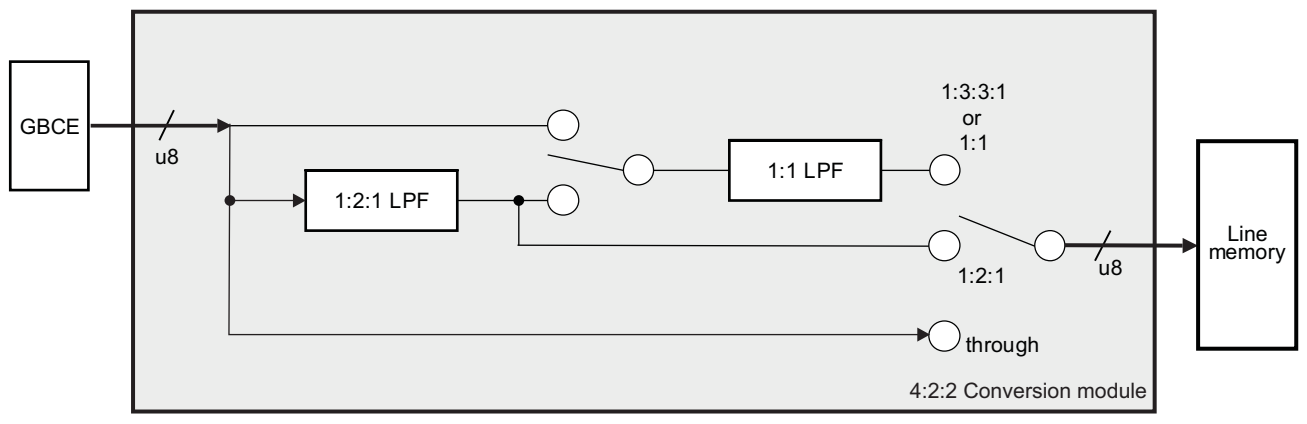

Figure 9-76. ISS ISP IPIPE Chroma Subsampling Position

camisp-164

Figure 9-77 is a block diagram of the 4:2:2 conversion module.

Figure 9-77. ISS ISP IPIPE 4:2:2 Conversion Module Block Diagram

camisp-165

9.3.3.5.13 ISS ISP IPIPE 2D Edge-Enhancer

NOTE: For the location of 2D edge-enhancer memory accesses, see [Section 9.3.3.11, ISS ISP Memory Mapping](#).

The edge-enhancer module operates on the Luma (Y data) component of images to improve the image quality and can be enabled from the `IPIPE_YEE_EN[0]` EN bit. Edges in input images are detected by a 2D high-pass filter, and its sharpness is increased by the value from a nonlinear table. [Figure 9-79](#) shows a block diagram of the Luma nonlinear edge-enhancer. Entry for the nonlinear table is 10-bit and the output is in signed 9-bit.

In edge-enhancer mode when `IPIPE_YEE_TYP[0]` SEL is set to 0, linear filter with programmable coefficient is applied to the Y input. Here, M is a 5 × 5 matrix with programmable coefficients (`IPIPE_YEE_MUL_xx`, where xx = 00, 01, 02, 10, 11, 12, 20, 21, 22). A down shift of high-pass filter is applied to the edge-enhancer from the `IPIPE_YEE_SHF[3:0]` SHF bit field (`shfHPF` in the formula in [Figure 9-78](#)).

Figure 9-78. ISS ISP IPIPE 2D Edge-Enhancer Linear Filter

$$HPF(h, v) = \left(\sum_{j=-2}^2 \sum_{i=-2}^2 M_{i,j} Y(h+i, v+j) \right) \gg shf_{HPF}$$

$$M = \begin{pmatrix} M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,0} & M_{1,0} & M_{0,0} & M_{1,0} & M_{2,0} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \end{pmatrix}$$

camisp-801

Then, the HPF value is shrunk by a threshold value (`u6`) specified by the `IPIPE_YEE_THR` register (`thresholdHPF` in the formula), and clipped to signed 10 bits to get the index for the LUT.

Figure 9-79. ISS ISP IPIPE 2D Edge-Enhancer Indexing

$$index = clip \left(shrink \left(HPF, threshold_{HPF} \right), -512, 511 \right)$$

$$shrink(x, threshold) = \begin{cases} x + threshold & x < -threshold \\ 0 & -threshold \leq x \leq threshold \\ x - threshold & threshold < x \end{cases}$$

$$clip(x, limit_{LOW}, limit_{HIGH}) = \begin{cases} -limit_{LOW} & x < -limit_{LOW} \\ x & -limit_{LOW} \leq x \leq limit_{HIGH} \\ limit_{HIGH} & limit_{HIGH} < x \end{cases}$$

camss-661

Moreover, the edge-enhancement intensity is looked up from the LUT through the formula shown in [Figure 9-80](#) and in [Table 9-214](#).

Figure 9-80. ISS ISP IPIPE 2D Edge Intensity LUT Formula

$$E_{int} = LUT[index]$$

camss-662

Figure 9-81 shows the LUT packing, and Figure 9-82 shows the 2D edge-enhancer block diagram.

Figure 9-81. ISS ISP IPIPE 2D Edge-Enhancer LUT Packing

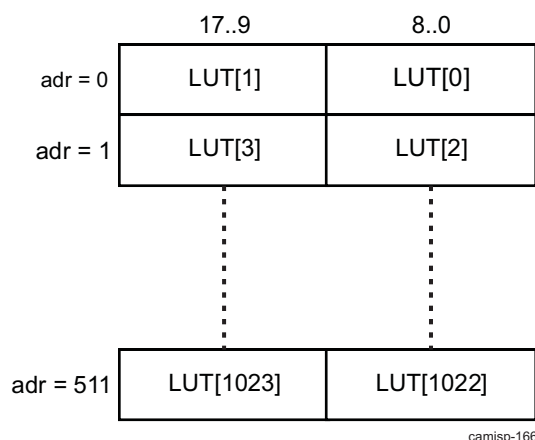

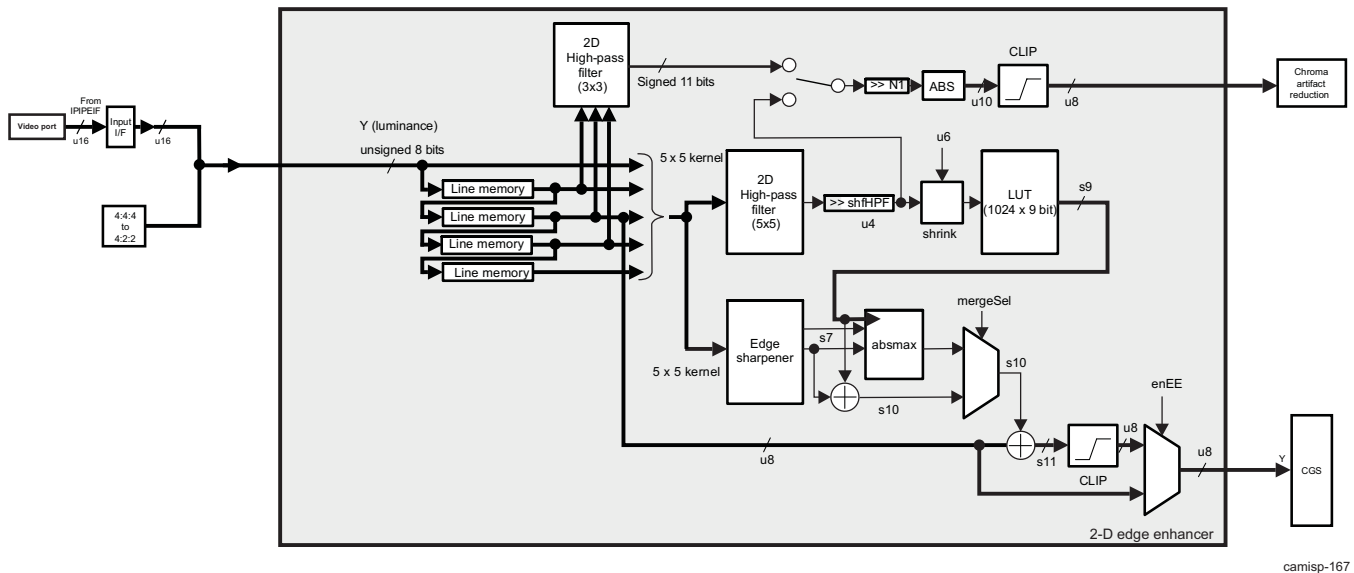

Figure 9-82. ISS ISP IPIPE 2D Edge-Enhancer Block Diagram

In edge sharpener mode, enabled when `IPIPE_YEE_TYP[0] SEL = 1`, edge clarity is enhanced without producing a halo artifact. In this module, edge intensity is derived by the 2D linear filter with fixed coefficients shown in Figure 9-83.

Figure 9-83. ISS ISP IPIPE Edge Sharpener Details

$$S_{i,j} = \begin{bmatrix} 0 & -1 & -2 & -1 & 0 \\ -1 & 0 & 2 & 0 & -1 \\ -2 & 2 & 8 & 2 & -2 \\ -1 & 0 & 2 & 0 & -1 \\ 0 & -1 & -2 & -1 & 0 \end{bmatrix}$$

$$sharpness(h,v) = clip \left(shrink \left(g \times \left(\sum_{j=-2}^2 \sum_{i=-2}^2 S_{i,j} Y(h+i, v+j) \right) \gg 3, threshold_{LOW} \right) \gg 6, -threshold_{HIGH}, threshold_{HIGH} \right)$$

The gain (g) and threshold values for the shrink/clip function ($threshold_{LOW}$, $threshold_{HIGH}$) are determined by the `IPIPE_YEE_E_GAN`, `IPIPE_YEE_E_THR_1`, and `IPIPE_YEE_E_THR_2` registers. The bit width of g and $threshold_{HIGH}$ is in U6, and $threshold_{LOW}$ is in U12Q6.

This edge intensity is then clipped by a threshold value in the formula shown in Figure 9-84.

Figure 9-84. ISS ISP IPIPE 2D Edge-Intensity Clipping Formula

$$S_{int} = \begin{cases} clip(sharpness, -grad, grad) & \text{Halo reduction on} \\ sharpness & \text{Halo reduction off} \end{cases}$$

The threshold value ($grad$) is a function of the activity around the target pixel, which is derived from gradient values. Gain and offset are specified by `IPIPE_YEE_G_GAN` and `IPIPE_YEE_G_OFT`

Capping with gradient value prevents overly enhancing edges, and suppresses halo artifacts around edges.

The output from edge-enhancer and edge sharpener are merged with the function shown in Figure 9-85.

Figure 9-85. ISS ISP IPIPE 2D Edge Enhancer and Sharpener Merger Formula

$$E_{merge} = \begin{cases} E_{int} + S_{int} & IPIPE_YEE_TYP[0]SEL = 0 \\ \text{absmax}(E_{int}, S_{int}) & IPIPE_YEE_TYP[0]SEL = 1 \end{cases}$$

$$\text{absmax}(x, y) = \begin{cases} x & \text{abs}(y) \leq \text{abs}(x) \\ y & \text{otherwise} \end{cases}$$

camisp-666

The E_{merge} value is added to the Y input value to make the final output.

For Chroma suppression, another 2D high-pass filter (HPF) is implemented. One of the four coefficient sets shown in [Figure 9-86](#) is selectable.

Figure 9-86. ISS ISP IPIPE 2D Edge Chroma-Suppression Coefficient Sets

$$\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad \text{or} \quad \begin{bmatrix} 0 & 1 & 0 \\ 1 & -4 & 1 \\ 0 & 1 & 0 \end{bmatrix}$$

camss-667

At the end of the edge-enhancer process, brightness and contrast adjustment are applied to the Y signal. The formula shown in [Figure 9-87](#) describes the process.

Figure 9-87. ISS ISP IPIPE 2D Edge-Brightness and Contrast Adjustments Formula

$$Y_{ctr_brt} = \text{clip8}(\text{clip8}(Y_{EE} \times \text{CTR}) \gg 4) + \text{BRT}$$

$$\text{clip8}(x) = \begin{cases} x & x \leq 255 \\ 255 & 255 < x \end{cases}$$

camisp-668

In the formula from [Figure 9-87](#), Y_{EE} is the output (Y) of the Edge-Enhancer, as shown in [Figure 9-82](#). CTR is a U8Q4 contrast enhancement factor (configured through the [IPIPE_YUV_ADJ\[7:0\]](#) CTR bit field), BRT is a U8 brightness enhancement factor (configured through the [IPIPE_YUV_ADJ\[15:8\]](#) BRT bit field), and Y_{CTR_BRT} is the output with brightness and contrast adjustment applied.

9.3.3.5.14 ISS ISP IPIPE Histogram

NOTE: The boxcar function can be used simultaneously with the histogram function if needed.

NOTE: For the locations of histogram memory access, see [Section 9.3.3.11, ISS ISP Memory Mapping](#).

The histogram module counts the number of pixels that have a value in a region and can be enabled from the [IPIPE_HST_EN\[0\]](#) EN bit. In addition to RAW input mode, Histogram can be performed on on YUV input in YUVtoRGB_MODE or YUV444_MODE ((SRC_FMT [FMT]=3, SRC_FMT [FMT2]=1 or 2). Moreover, if enabled, the [IPIPE_HST_MODE](#) register can be set to work constantly or one time. If the [IPIPE_HST_MODE\[0\]](#) OST bit is set to 1, the histogram is disabled by clearing the [IPIPE_HST_EN\[0\]](#) EN bit to 0 after one run (one-shot mode).

After enabling the module, the following features are available:

- The data to be summed is taken from the DPC memory or RGB2YCbCr module. The choice is made in the [IPIPE_HST_SEL\[2\]](#) SEL bit.
- When data are collected from the DPC memory, the sampled colors are R/G/B/Y. Y is derived in the following method:

$$Y = (\text{HST_MUL_R} * R + \text{HST_MUL_GR} * Gr + \text{HST_MUL_GB} * Gb + \text{HST_MUL_B} * B) \quad (1)$$

For the G histogram, Gb, Gr, or the average is used, through the `IPIPE_HST_SEL[1:0]` TYP bit field.

- Two sets of 512 × 20-bit memory are used.
- The number of bins can be set from 32 to 256 in the `IPIPE_HST_PARA[13:12]` BIN bit field.
- The number of regions (areas) from 1 to 4; each region can be enabled through `IPIPE_HST_PARA[x]` RGNx (where x = 0 to 3). The positions of the regions are defined in `IPIPE_HST_x_VPS` and `IPIPE_HST_x_HPS`, and the vertical and horizontal size are defined by `IPIPE_HST_x_VSZ` and `IPIPE_HST_x_HSZ`, respectively (where x = 0 to 3).
- The number of regions × the number of bins ≤ 256.
- Each region can be turned on/off counting.
- The regions have priority orders.
- Each region has its own start coordinate X/Y (12 bits) and horizontal/vertical sizes (12 bits)
- When regions are overlapped, the value in the overlapped region is accumulated only in the region with the highest priority.
- The number of colors to be counted is from 1 to 4. Each color in all regions can be turned off counting (the `IPIPE_HST_PARA[7:4]` bit field).
- The value of each pixel is down-shifted (0–11) before counting using the `IPIPE_HST_PARA[11:8]` SHF bit field.
- When the value of a bin reaches ($2^{20} - 1$), the value is saturated until the memory is cleared.
- Number of bins: 32, 64, 128, or 256

The histogram memory can be cleared at the VD signal. When the memory is cleared, the first line of each frame cannot be sampled by the histogram if the width of the frame is larger than 512. If the width of the frame is smaller than 512, the first ceil (512/width) lines cannot be collected, where ceil(x) is the smallest integer value above x. If the clearing function is not enabled, the histogram bins are accumulated over the previous values.

The histogram has two banks of memories, which can be switched alternatively. The two memory banks are slipped into four histogram memory tables. Only two tables can be used at a time: output memory tables 0 and 1, or tables 2 and 3. To initialize tables, set the `IPIPE_HST_TBL[1]` CLR bit to 1, and to select which set of tables to uses, switch the `IPIPE_HST_TBL[0]` SEL bit between 0 and 1.

The mapping of histogram memory is shown in [Table 9-215](#). The switching of the two memories is done through `HST_TBL[SEL]`, which is latched at VD. Example of the use of this switching is as following

- For frame-0, set `HST_TBL [SEL]=0`. Histogram engine uses memory 0 and 1 (Bank 0).
- After IPIPE starts processing frame-0 and the register update is allowed, which is indicated by `ipipe_int_reg`, CPU sets `HST_TBL [SEL]=1`. This makes histogram module use memory 2 and 3 in the next frame.
- After IPIPE completes the histogram collection of frame-0 (`ipipe_int_hst`), CPU or DMA starts transferring memory 0 and 1 to SDRAM.
- Repeat step 2 and 3 for each of the following frames. `HST_TBL [SEL]` changes alternatively every frame. CPU/DMA accesses the memory that is not accessed by the histogram module.

Table 9-215. ISS ISP IPIPE Histogram Memory Mapping

Memory #	Address	Histogram Table	Table Address

Histogram memory #3	0x01FFh	Histogram 1 (Bank 1)	Table address = 0x01FFh

A gain for each color can be applied using the IPIPE_HST_MUL_x registers, where x = R, GR, GB, or B.

9.3.3.5.15 ISS ISP IPIPE Boxcar

The boxcar module generates a boxcar by taking mosaic image data and averaging the red, green, and blue pixels in an 8 × 8 or 16 × 16 block to produce one red, green, and blue output, as shown in [Figure 9-88](#) and in [Figure 9-89](#). Here, similar to the histogram module, the boxcar is enabled from the IPIPE_BOX_EN[0] EN bit, and if the mode is set to run once (one shot) (IPIPE_BOX_MODE[0] OST = 1), the enable bit is cleared after the run. The size of the blocks is determined from the IPIPE_BOX_SHF[0] SEL bit, where if set to 0 = 8 × 8, and 1 = 16 × 16.

The result of this operation is a full-color image with (1/64) or (1/256) area of the original image. The maximum input horizontal width is 8190 pixels when a 16 × 16 block is used; the width is 4096 when an 8 × 8 block is used. Also, the image size (width and height) must be a multiple of 16 for a 16 × 16 block, and a multiple of 8 for an 8 × 8 block. Boxcar operation works on 12-bit Bayer data and outputs 16-bit data. The output data is 48-bit RGB data for each 8 × 8 or 16 × 16 block. The 48-bit data is aligned in 64-bit format in SDRAM as shown in [Figure 9-90](#). The first address of SDRAM access is specified by the IPIPE_BOX_SDR_SAD_H and IPIPE_BOX_SDR_SAD_L registers. The output data are written to SDRAM continuously line by line; there is no address offset between lines. After the image transfer of each frame completes, the ipipe_eof signal is sent to buffer logic. This signal is issued at the same timing as ipipe_int_dma.

Figure 9-88. ISS ISP IPIPE Boxcar Operation (8 × 8 Block)

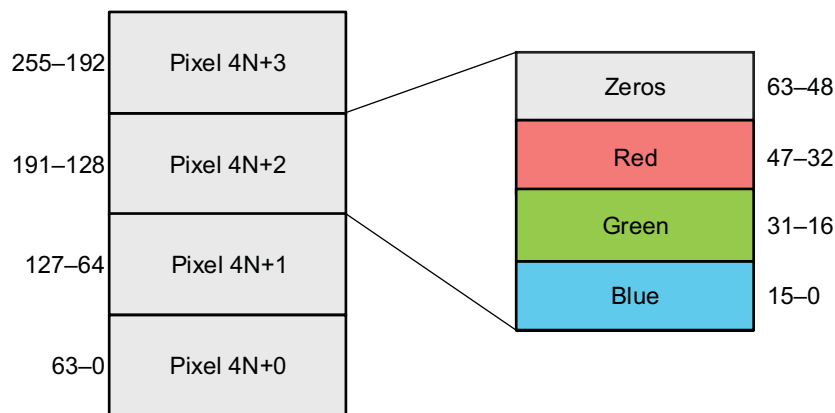

camisp-192

Figure 9-89. ISS ISP IPIPE Boxcar Operation (16 × 16 Block)

camisp-193

Figure 9-90. ISS ISP IPIPE Boxcar Data Packing in SDRAM

camisp-194

The right-shift value is specified by the `IPIPE_BOX_SHF` register, which has a range of 0 to 4. (The shift down is performed to fit the 20-bit accumulated value into 16-bit output.) For green signal processing, a divide-by-two operation rounds off the LSB.

9.3.3.6 ISS ISP RSZ Functional Description

9.3.3.6.1 ISS ISP RSZ Overview

The RSZ module rescales images into various sizes ranging from x1/4096 scale-down to x16 scale-up. The RSZ data slave interfaces support a parallel VP. The RSZ module can produce two output images simultaneously, because there are two independent resizer engines. The input data used by the two resizer engines is the same.

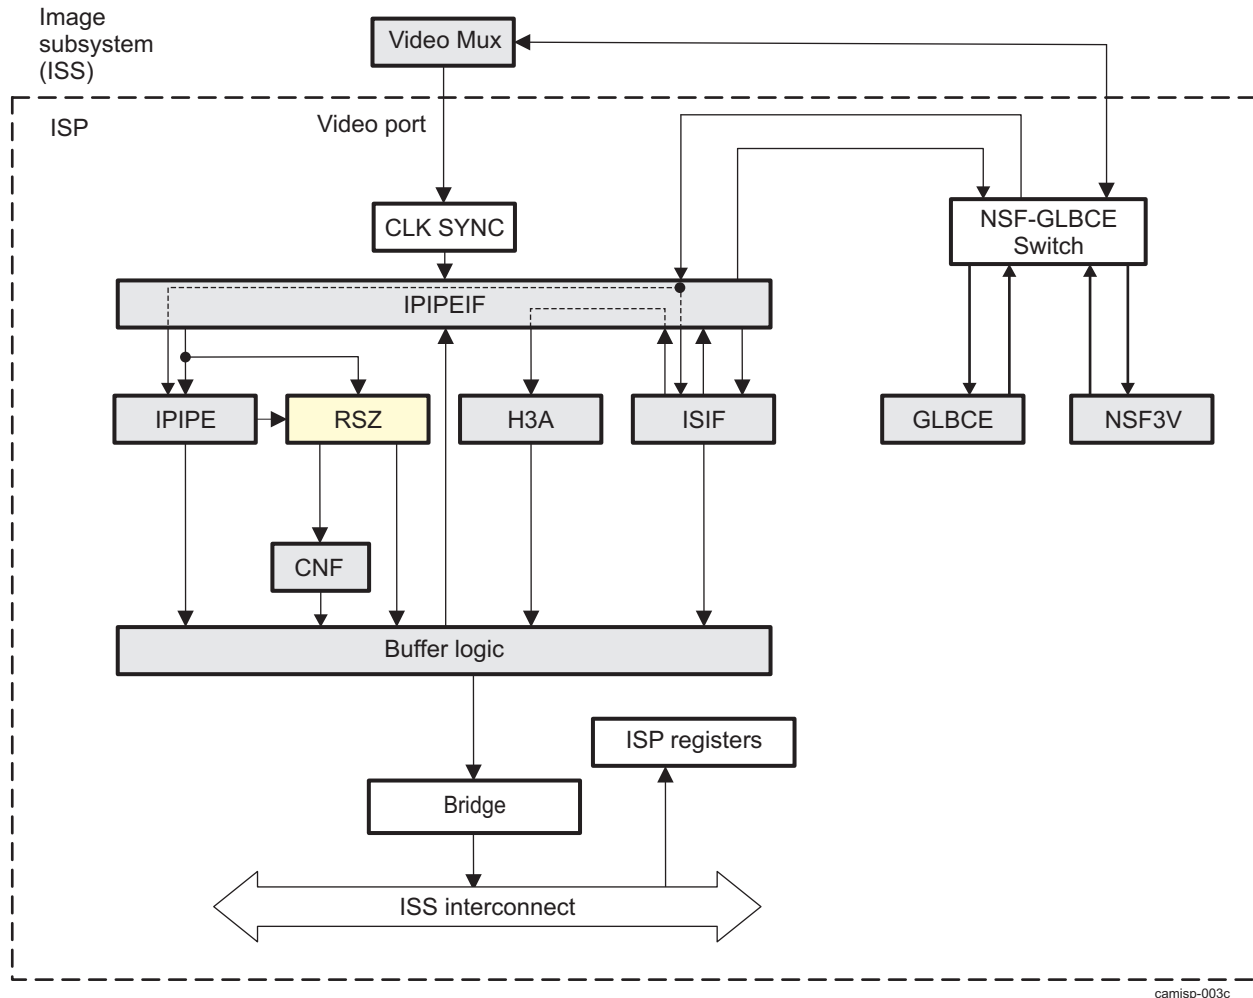

The RSZ module has the following capabilities:

- Input/output data formats:
 - Common input data for the two resizer engines
 - Independent output data formats for the two resizer engines
 - Supports YUV4:2:2 input and then supports YUV4:2:2/YUV4:2:0 or RGB5:6:5/ARGB32 output:
 - Output rates up to 532 MPix/s for YUV4:2:2/YUV4:2:0 or RGB5:6:5 output
 - Output rates up to 532 MPix/s for ARGB32 output
 - Supports YUV4:2:0 input data and then supports only YUV4:2:0
 - YUV4:2:0 input format not supported natively:
 - Two passes required: Luma followed by Chroma or vice versa
 - Input and output rates up to 106.4 MPix/s in this configuration (YUV4:2:0)
 - Only supported from memory to memory
 - Supports RAW Bayer input and RAW Bayer output:
 - RAW format invariant. Takes whichever RAW format at the input and writes it out unmodified: 16 bits are read, 16 bits are written out.
 - No resizing can take place on RAW data.
- Resizer capabilities:
 - Input image cropping:
 - Common for the two resizer engines: Same input data before and after cropping
 - Supported on YUV4:2:2 and RAW data formats
 - Supported on pass-through mode data path
 - Supported on bypass mode data path
 - Dual resizer engines: RSZ-A and RSZ-B:
 - Up to x20 upsampling and x1/4096 downsampling on both engines
 - Up to 532 MHz pixel throughput on both resizer engines
 - Programmable data rate control to smooth the peak memory bandwidth
 - RSZ-A: Horizontal resolution of up to 8K pixels on RSZ-A
 - RSZ-B: Horizontal resolution of up to 8K pixels on RSZ-B
 - Independent Y and Cb/Cr phases on horizontal and vertical axis:
 - Enables to take care of different YUV4:2:0 phases used in different video formats
 - Enables frame division mode: Images can be stitched together with the right phase.
 - Rescaling: two modes supported:
 - Normal mode for upscale and downscale: Higher flexibility but lower downscale quality
 - Downscale mode for downscale only: Lower flexibility but higher downscale quality
 - Filtering: two modes supported:
 - Independent settings for the horizontal and vertical directions
 - 3-tap low-pass filter with 2-tap linear interpolation
 - 4-tap cubic interpolation
 - Flip support of the output image:

- Horizontal flip
- Vertical flip
- Pixel duplication on the top/bottom, left/right sides: Avoids losing pixels at the image boundaries because of the filtering
- Support pass-through and bypass modes: Resizer engines bypassed:
 - Pass-through mode
 - RAW and YUV4:2:2 data support
 - Lower power consumption mode to transfer data to memory
 - Can transfer images larger than 8K pixels to memory
 - Bypass mode
 - RAW and YUV4:2:2 data support
 - Input buffer used. Can benefit from additional buffering in case the BL module memory is not big enough and back pressure occurs.
- Slave data interface: VP interface:
 - Two VP interfaces: The programming model selects which VP is used to input data to the RSZ module. Both VPs cannot be active simultaneously.
 - VP 1: Typically connected to the IPIPE module.
 - VP 2: Typically connected to the IPIPEIF module.
 - Up to 532 MHz pixel clock
- Master data interface:
 - Two interfaces to the BL module:
 - Up to 532 MHz
 - 32-bit-wide, 32-byte-long requests
 - Accesses are aligned on 32-byte boundaries.
 - Used to transfer data to memory
 - Each interface is dedicated to a single output image.
 - Addressing modes:
 - Linear
 - Circular
- Chroma Noise Filter
 - RSZ-A works with CNF (Chroma Noise Filter) to filter Cb/Cr of YCbCr420 output
 - Filtering is done by the external CNF module. RSZ provides the tap-in/out points for CNF function, and control of CNF enable/disable and CDS enable/disable
 - CNF function on RSZA and RSZB can be independently programmed
- Configuration interface:
 - Up to 106,4 MHz
 - 32 bits wide
 - Used to configure the resizer registers
- Power management: Independent clock domains for the two resizers (Each resizer engine can be gated off separately)
- Error management: FIFO overflow detection on the input buffers

[Figure 9-91](#) show the RSZ module connections to other submodules of the ISP.

Figure 9-91. ISS ISP RSZ High-Level Diagram

camisp-003c

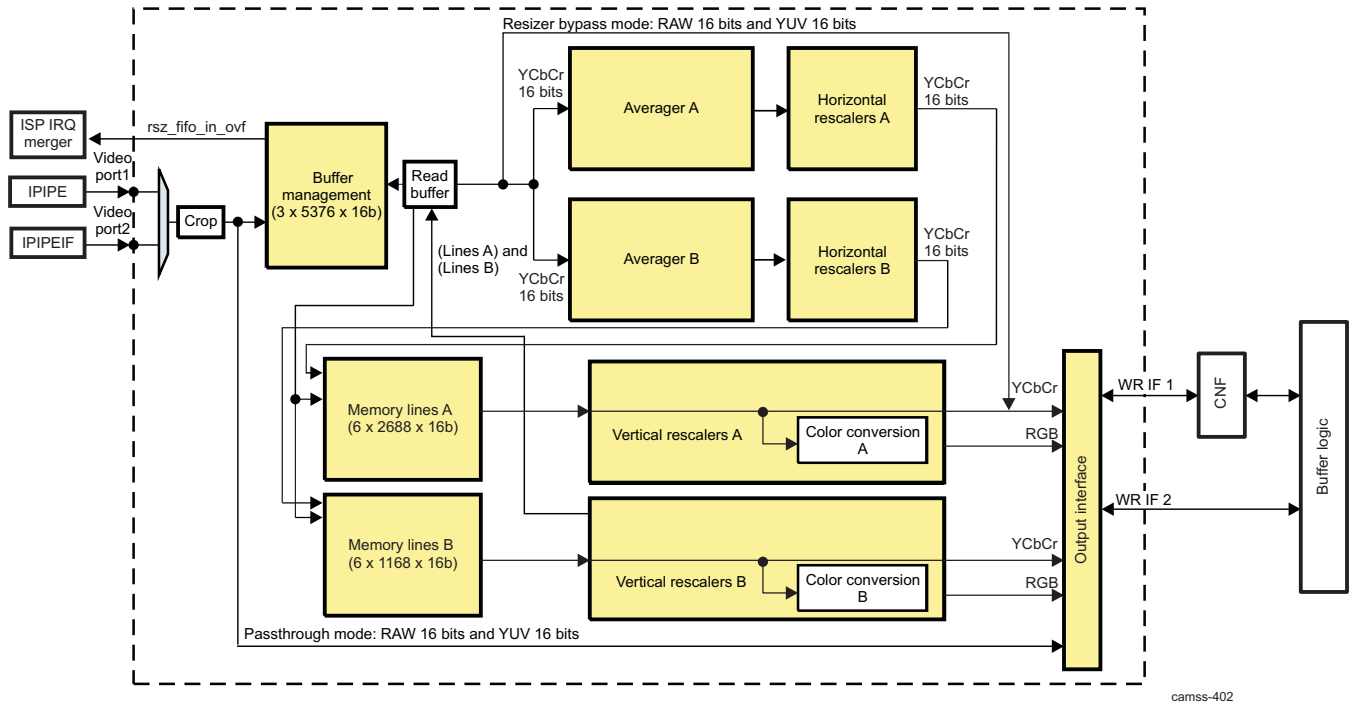

9.3.3.6.2 ISS ISP RSZ Top-Level Block Diagram

Figure 9-92 is the top-level block diagram of the RSZ module. The RSZ module comprises the following submodules: cropping, input data buffering, data requestor, averager, data saturation, and resizer interpolation (comprised of horizontal rescaler, vertical rescaler, color conversion, and output interface) (see the following sections for more information).

The RSZ module comprises two independent resizer engines with the same capabilities (except for the memory line size). The input data can come from VP 1 or VP 2. Software must determine and control which interface is selected.

The RSZ module includes one VBUSP slave port, which is used to control the RSZ registers. It also includes two MTC master ports, which are used to pass the pixels to CFN module for RSZ1 or to the BL for RSZ2. If not needed CFN module can be bypassed. The BL in turn creates the burst requests to the memory subsystem (see Section 9.3.3.6.3, ISS ISP RSZ Interfaces).

Figure 9-92. ISS ISP RSZ Top-Level Block Diagram

9.3.3.6.3 ISS ISP RSZ Interfaces

The RSZ module has the following data interfaces:

- One 32-bit read/write point-to-point pending VBUSP interface
- Two slave VP interfaces for transport YUV and RAW data
- Two MTC interfaces to BL for RSZ-A and RSZ-B, with only write capabilities
- Interface of RSZ1 to CNF

9.3.3.6.3.1 ISS ISP RSZ VBUSP Interface

The VBUSP interface is a 32-bit read/write capable interface. The VBUSP interface must be programmed in a way that back-to-back requests are possible for read and write. The `RSZ_GCK_MMR[0]` MMR bit enables the memory register access from the VBUSP interface to enable transfer and signal such as MMR request, direction, enable write/read data can be enabled.

9.3.3.6.3.2 ISS ISP RSZ Video Port Interfaces

The VP interfaces are slave interfaces; one is connected to IPIPE, and the other to IPIPEIF (or GLBCE from the NSF-GLBCE data flow switch). These interfaces are for data transfer. Table 9-216 lists the format supported across IPIPE/IPIPEIF and RSZ. Signals coming from IPIPE and IPIPEIF can be write-enable signals. The `RSZ_SRC_MODE[1]` WRT bit is set whether or not the write enable signals are considered. This is a line-valid qualifier. This signal is sampled on the rising edge of HD, and the value is used for the full line.

Table 9-216. ISS ISP RSZ VP Supported Formats

	VP Signals: From IPIPE and IPIPEIF(or GLBCE) Modules (dat[15:0] Register)															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RAW16	R15	R14	R13	R12	R11	R10	R9	R8	R7	R6	R5	R4	R3	R2	R1	R0
YUV4:2:2 16 bits	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Cb7 Cr7	Cb6 Cr6	Cb5 Cr5	Cb4 Cr4	Cb3 Cr3	Cb2 Cr2	Cb1 Cr1	Cb0 Cr0

Table 9-216. ISS ISP RSZ VP Supported Formats (continued)

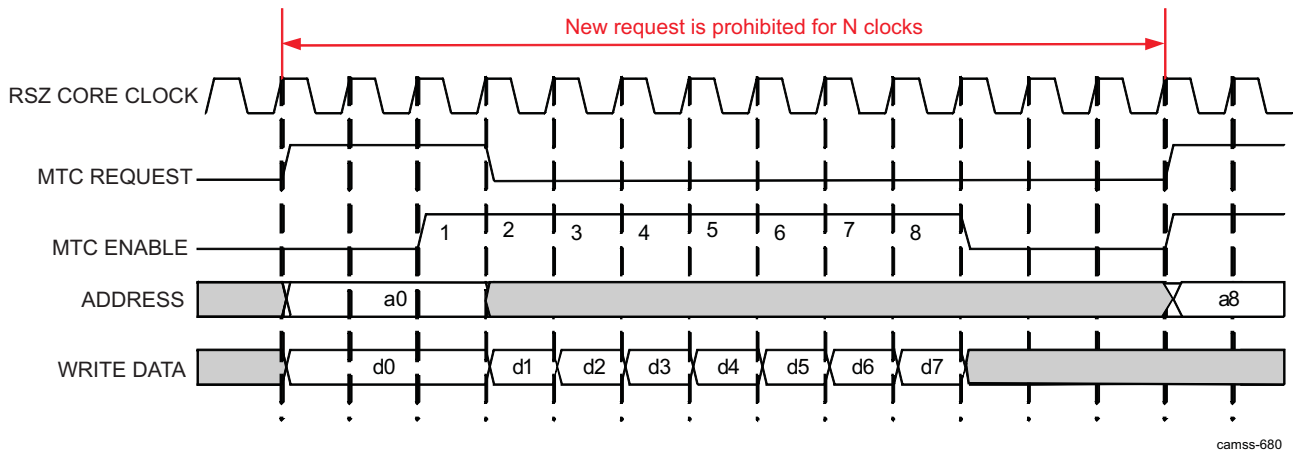

YUV4:2:0 Y data	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Low	Low	Low	Low	Low	Low	Low	Low
YUV4:2:0 Cb/Cr data	Low	Low	Low	Low	Low	Low	Low	Low	Cb7 Cr7	Cb6 Cr6	Cb5 Cr5	Cb4 Cr4	Cb3 Cr3	Cb2 Cr2	Cb1 Cr1	Cb0 Cr0

NOTE: The formats are set from the IPIPE and IPIPEIF registers. For more information, see [Section 9.3.3.5, ISS ISP IPIPE Functional Description](#), and [Section 9.3.3.4, ISS ISP IPIPEIF Functional Description](#).

9.3.3.6.3.3 ISS ISP RSZ MTC Interfaces

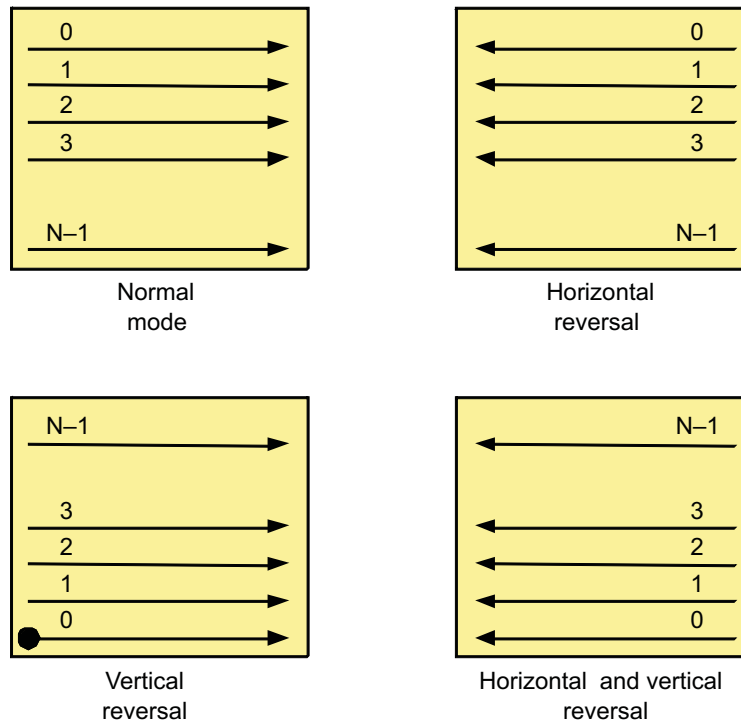

The RSZ module includes two write-only MTC interfaces. Their implementation enables passing a maximum of eight 32-byte requests in 10 clock cycles. The RSZ must be programmed to obtain smooth and average bandwidth to buffer logic module by setting a minimum interval between two successive requests (set the `RSZ_DMA_RZA[15:0]` RZA and `RSZ_DMA_RZB[15:0]` RZB bit fields for the A and B resizers as appropriate). This setting is not expected to be dynamic. It can be a fixed setting from request to request and frame to frame. When the bandwidth is set appropriately, between the first valid translated pixel and the EOF signal sent to buffer logic, the `RSZ_DMA_STA[0]` STATUS bit can be seen, and it is high if the transfer over the MTC interfaces is active. [Figure 9-93](#) shows how `RSZ_DMA_RZx` for resizers A and B affects the MTC data request generator.

Figure 9-93. ISS ISP RSZ MTC DMA Bandwidth Control

[Figure 9-94](#) shows the pixel order in memory written by the MTC. The arrows do not represent the order in which data is written. Data are always written from left to right, whether horizontal reversal is enabled or not.

Figure 9-94. ISS ISP RSZ MTC Image Data Storage Pixel Order

camss-684

The RSZ MTC interfaces can be stalled by the input MTC STALL signal. The assertion of the MTC STALL signal is a result of a hardware mechanism that monitors the CBUFF module to prevent its overflow. When this signal is asserted, the current 32-byte MTC request is finished and then the RSZ MTC output ports are stalled. For further details on the output ports, see [Section 9.3.3.6.7, ISS ISP RSZ Output Interface](#).

9.3.3.6.3.4 ISS ISP RSZ CNF Interface

When CNF receives a pixel data from RSZ, it asserts acknowledge signal. The acknowledge and data receive can be at the same clock, allowing 1pix/cycle transfer. When CNF sends a pixel back to RSZ, it raises req signal on the same clock cycle as the data. RSZ raises ACK signal when it receives the data. Req and Ack can be at the same clock to enable 1 pix/cycle transfer.

Table 9-217. ISS ISP RSZ CNF Data Interfaces (CNF output to RSZ)

Signal	Direction (from RSZ)	Description	Format
RZAtoCNFA_DOUT	OUT	RZA to CNFA data	8bit (Cb or Cr per cycle)
RZAtoCNFA_ACK	OUT	Acknowledge signal of the data from RZA to CNFA	1 bit. 1 cycle active high pulse
RZAtoCNFA_REQ	IN	Request signal of the data from RZA to CNFA	
CNFAtoRZA_DOUT	IN	CNFA to RZA data	8bit (Cb or Cr per cycle)
CNFAtoRZA_REQ	IN	Request signal of the data from CNFA to RZA	1 bit. 1 cycle active high pulse
CNFAtoRZA_ACK	OUT	Acknowledge signal of the data from RZA to CNFA	1 bit. 1 cycle active high pulse
CNFA_HE	IN	Line End signal from CNFA to RZA	1 bit. 1 cycle active high pulse
CNFA_VE	IN	Frame End signal from CNFA to RZA	1 bit. 1 cycle active high pulse

The following configuration are sent to CNF from ISP-Top (ISP6_SYS3)

- [ISP_CNF_EN\[0\]](#) CNFA_EN
- [ISP_CNF_EN\[1\]](#) CNFA_CDSEN

9.3.3.6.4 ISS ISP RSZ ICM Handshake Signals

The RESIZER module can do handshaking with ICM. For this purpose, RESIZER has two input signals (P_START_A/B) and two output signals (P_DONE_A/B) for each channel.

Table 9-218. ISS ISP RSZ ICM Handshake Interfaces

Signal name	Direction	Description
P_START_A	Input	Process start signal from ICM to RSZ_A. This signal is used for YUV422 mode and Y channel of YUV420.
P_DONE_A	Output	Process done signal from RSZ_A to ICM. This signal is used for YUV422 mode and Y channel of YUV420.
P_DONE_AC	Output	Process done signal from RSZ_A Chroma Channel to ICM. This signal is used only for C channel of YUV420.
P_START_B	Input	Process start signal from ICM to RSZ_B. This signal is used for YUV422 mode and Y channel of YUV420. In ISS configuration, this signal is tied '1' at ISS level.
P_DONE_B	Output	Process done signal from RSZ_B to ICM. This signal is used for YUV422 mode and Y channel of YUV420. In ISS6 configuration, this signal is left open.
P_DONE_BC	Output	Process done signal from RSZ_B Chroma Channel to ICM. This signal is used only for C channel of YUV420.

P_DONE_X (X=A/AC/B/BC) is high for 2 to 4 ISS_MAIN_FCLK cycles.

In ISS implementation, handshake between RSZB and ICM is not implemented. Therefore, P_START_B is tied "high" at ISS6 level. RSZ must be designed so that, it can operate if any of P_START_A/AC/B/BC is always "1".

When handshaking is enabled ([RSZ_IRQ_RZA\[16\]](#) ICMA_EN=1 or [RSZ_IRQ_RZB\[16\]](#) ICMB_EN=1), RESIZE operate its RSZ_A output port in the following manner.

1. RSZ waits until P_START_A signal input from ICM.
2. RSZ output [RSZ_IRQ_RZA](#).RZA lines to SDRAM/SRAM
3. RSZ output P_DONE_A signal (2 to 4 ISS_MAIN_FCLK)
4. Repeat the cycle 1 through 3 until RSZ reaches the end of frame.
5. If [RSZ_IRQ_RZA](#).ICMA_EOF=1, issue P_DONE_A at the end of frame if it is not the end of RZA cycle

For RSZ_B, the process is exactly the same except the signals are P_START_B and P_DONE_B, and the parameters is [RSZ_IRQ_RZB](#) RZB. ([RSZ_IRQ_RZA](#) RZA and [RSZ_IRQ_RZB](#) RZB are shared with IRQ cycles.)

If P_START_A/B signal is not asserted for an extended period, and if the input buffer becomes close to buffer over flow, RSZ_INPUT_STALL signal must be asserted to suspend the input stream

RSZ starts ICM handshake and starts checking P_START_x signals only after it is enabled.

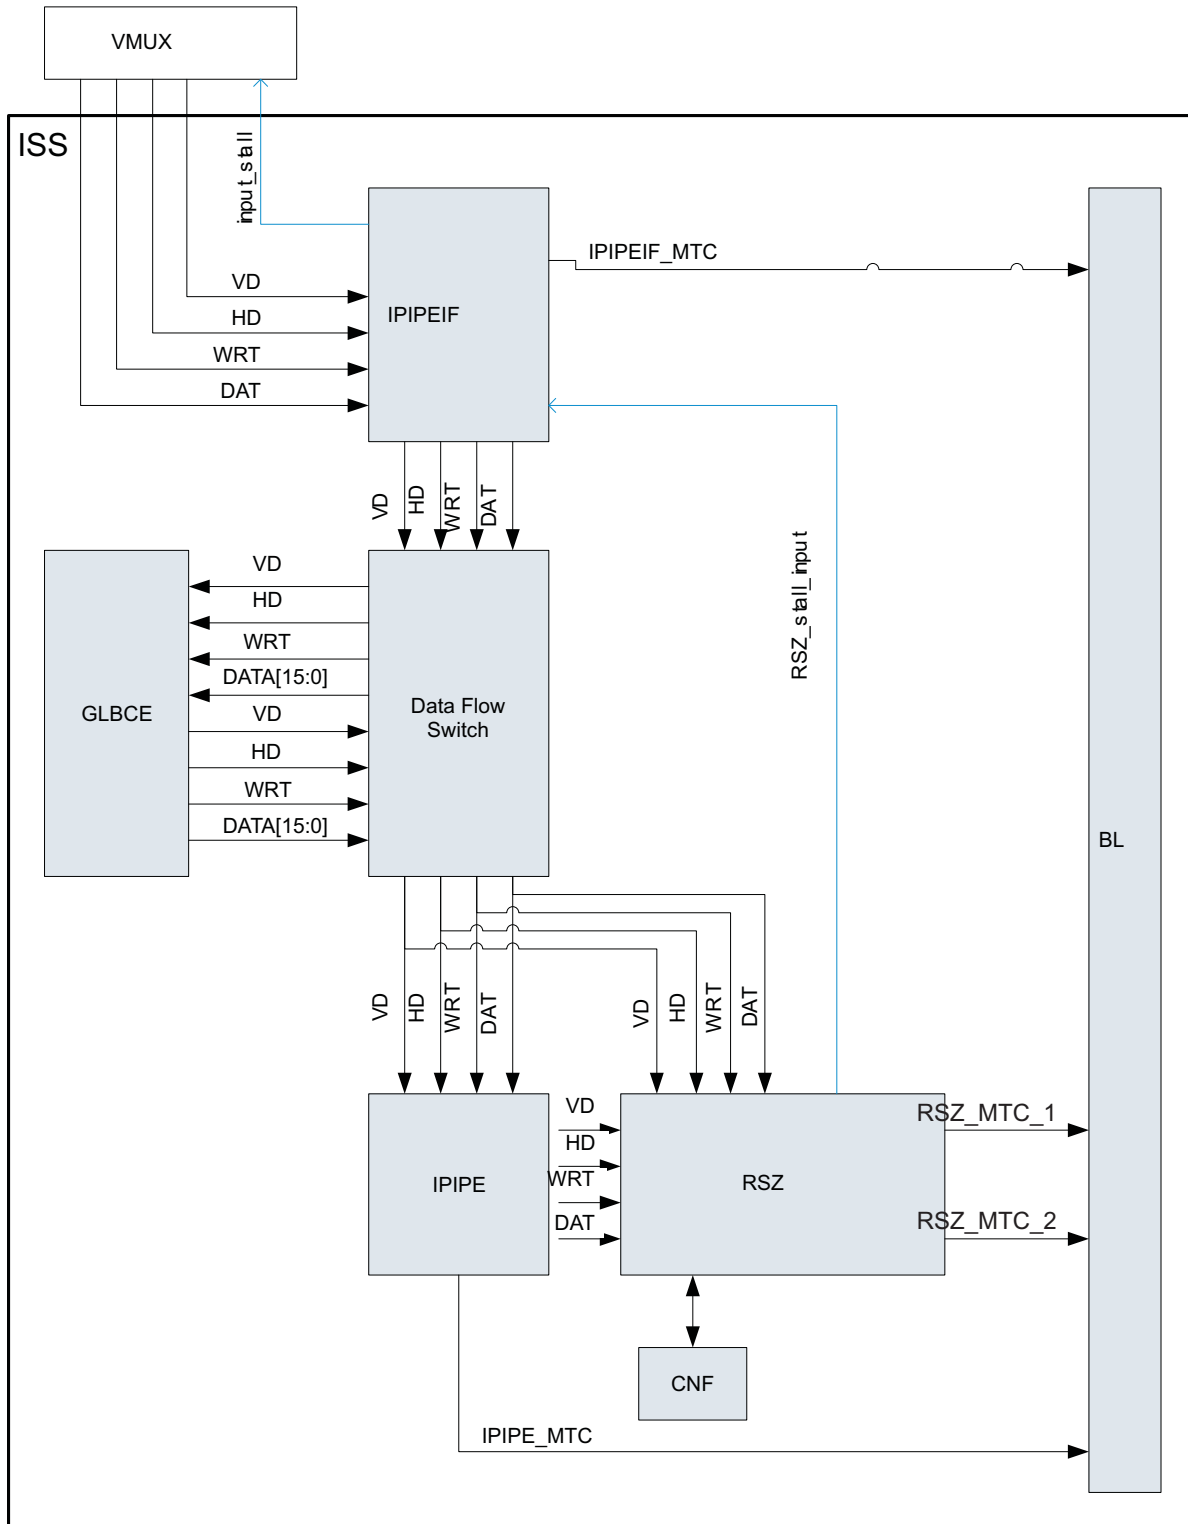

Example-1: RSZ in single shot mode: RSZ is enabled at the frame start after the first crop, and this timing is notified to SW through rsz_int_reg event. If P_START is sent to RSZ before this moment (rsz_int_reg), it is ignored. ICM Handshake must start after rsz_int_reg interrupt.

Example-2: RSZ in single shot mode: For each frame, RSZ is enabled at the frame start after the first crop (= rsz_int_reg issue timing). Any P_START received between the EOF of the last frame and the current frame start (rsz_int_reg) is ignored. ICM handshake for each frame must be started after rsz_int_reg interrupt.

9.3.3.6.5 ISS ISP RSZ Integration

Figure 9-95 shows how the VP and interfaces of the RSZ module are connected to surrounding modules at the ISP level. The RSZ module gets data from the IPIPEIF module or IPIPE module.

Figure 9-95. ISS ISP RSZ Module Integration: High-Level Summary

camss-400

The following constraints apply to the RSZ module:

- The data coming from the IPIPEIF module can be RAW or YUV4:2:2 data. Because the RSZ module can rescale only YUV4:2:2 data, the RSZ module must be configured in pass-through mode when RAW data is received on VP 2. It is possible to bypass the resizer engine if YUV4:2:2 data is sent but

rescaling is not needed (bypass mode).

- The data coming from the IPIPE module can be RAW or YUV4:2:2 data. Eventually, YUV4:2:0 data can be sent through this path, but the data must be sent in two passes. Because the RSZ module can rescale only YUV4:2:2 data, the RSZ module must be configured in pass-through mode when RAW data is received on VP 1. It is possible to bypass the resizer engine if YUV4:2:2 data is sent but rescaling is not needed (bypass mode).

VP 2 provides a way to bypass the IPIPE module when YUV4:2:2 data is received from the images sensor or when YUV4:2:2 is read back from memory with the CAL_B or ISIF module.

Table 9-219 summarizes the different RSZ configuration possibilities as a function of the input data format.

Table 9-219. ISS ISP RSZ Data Flow vs. Input Data Format Constraints

VP 1 Data Format	VP 2 Data Format	RSZ-A Configuration	RSZ-B Configuration	Comments
RAW	N/A	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
N/A	RAW	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
YUV4:2:2	N/A	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
YUV4:2:2	N/A	Enabled	Disabled	One output image
YUV4:2:2	N/A	Disabled	Enabled	One output image
YUV4:2:2	N/A	Enabled	Enabled	Two output images
N/A	YUV4:2:2	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
N/A	YUV4:2:2	Enabled	Disabled	One output image
N/A	YUV4:2:2	Disabled	Enabled	One output image
N/A	YUV4:2:2	Enabled	Enabled	Two output images

9.3.3.6.6 ISS ISP RSZ Functional Description

To start up, the RSZ configuration can be set from the [RSZ_SYSCONFIG](#) register, which provides enabling the RSZ-A and RSZ-B clocks. The RSZ module does not have stand-alone reset and status check. Software reset must be done at the ISP level. Moreover, when enabled, the RSZ module can control the input data buffer, and when the `rsz_stall_input` signals are set from the [RSZ_IN_FIFO_CTRL](#) register, the RSZ module generates a stall signal that can be used by the master module sending data to the RSZ module when the data threshold is too high.

The [RSZ_SRC_EN\[0\]](#) EN bit starts the resizer processing. If the processing mode is set to one shot (one run and then turn off) from the [RSZ_SRC_MODE\[0\]](#) OST bit, the EN bit is cleared to 0.

The RSZ module can be configured to be bypassed in certain cases (see [Figure 9-95](#) for the module constraints) from the [RSZ_SRC_FMT0\[1\]](#) BYPASS bit. The data can be sent directly from here to the output interface (bypass mode) or imported to the module buffer, but not manipulated and sent to the output interface (pass-through mode). The master device sending data to the RSZ can be switched between IPIPEIF and IPIPE using the [RSZ_SRC_FMT0\[0\]](#) SEL bit. The RSZ understanding of the data input is set from the [RSZ_SRC_FMT1](#) register (for more information, see [Table 9-221](#)). The [RSZ_SEQ.VRVX](#) and [RSZ_SEQ.HRVX](#) registers can be set to flip the image horizontally or vertically, respectively (see [Figure 9-94](#)).

Depending on the mode to which the RSZ is set, the core clock can be enabled from the [RSZ_GCK_SDR](#) register. [Table 9-220](#) summarizes the behavior of the RSZ module for the different settings.

Table 9-220. ISS ISP RSZ Module Modes: Register Settings

Configuration Number	RSZ_SR C_EN	RZA_EN	RZA_CL K_EN	RZB_EN	RZB_CLK_EN	RSZ_GC K_SDR_CORE	RSZ_SR C_FMT0 .BYPASS	Comments

Table 9-220. ISS ISP RSZ Module Modes: Register Settings (continued)

0	0	X	X	X	X	X	X	Data cannot go through the RSZ module. Interrupts are not issued.
1	1	0	X	0	X	1	0	RSZ-A is disabled. RSZ-B is disabled. It is best to have RZA_EN = RZB_EN = 0 to save power, but RZA_EN = RZB_EN = 1 is also supported.
2	1	1	1	0	X	1	0	This configuration is supported but does not make sense because data cannot go through the module. RSZ-A is enabled. RSZ-B is disabled. It is best to have RZB_EN = 0 to save power, but RZB_EN = 1 is supported as well.
3	1	0	X	1	1	1	0	RSZ-A is disabled. RSZ-B is enabled. It is best to have RZA_EN = 0 to save power, but RZA_EN = 1 is also supported.
4	1	1	1	1	1	1	0	Resizer A is enabled. Resizer B is enabled.
5	1	X	X	X	X	0	0	Bypass mode is enabled. Resizer core functional clock is disabled.
6	1	X	X	X	X	0	1	Pass-through mode enabled. Resizer core functional clock is disabled.
7	1	X	X	X	X	1	1	Pass-through mode is enabled. Resizer core functional clock is enabled. Not a preferred configuration. Configuration 6 saves power.

Table 9-221. ISS ISP RSZ Module Input Control: Register Settings

RSZ_SRC_FMT1.IN420	RSZ_SRC_FMT1.COL	Comments
0	X	YUV4:2:2 input. Chroma is co-sited.
1	0	YUV4:2:0 input. Valid data is Y, C is dummy. On the VP, YUV4:2:2 data is always assumed.
1	1	YUV4:2:0 input. Valid data is C, Y is dummy. On the VP, YUV4:2:2 data is always assumed.

The [RSZ_YUV_PHS\[0\]](#) POS bit sets the Chroma output. The RSZ module does not change the relative position of the Chroma samples versus the Luma samples between the input and output, and the Chroma position at the output of the IPIPE module and at the output of the RSZ module must be identical. In other words, [RSZ_YUV_PHS.POS = IPIPE_YUV_PHS.POS](#).

Settings are common for both resizer engines inside the RSZ module. Each engine (RSZ-A or RSZ-B) can be enabled from the [RZx_EN](#) register: select the mode from [RZx_MODE](#), and select the input and output in the YUV color scheme from the [RZx_420](#) register (valid only if YUV4:2:2 is the input set from [RSZ_SRC_FMT1.IN420](#)). [Table 9-222](#) summarizes the combination of settings available in the [RZx_420](#) register.

Table 9-222. ISS ISP RSZ-A/RSZ-B Output Format Selection

RZx_420.YEN	RZx_420.CEN	Comments
0	0	Input is YUV4:2:2. Output is YUV4:2:2 if RZX_RGB_EN = 0 and RGB if RZB_RGB_EN = 1 .

Table 9-222. ISS ISP RSZ-A/RSZ-B Output Format Selection (continued)

RZx_420.YEN	RZx_420.CEN	Comments
0	1	Input is YUV4:2:2. Output is the Chroma of YUV4:2:0. RZX_RGB_EN is ignored. Must be used to rescale YUV4:2:0 data: First/second pass
1	0	Input is YUV4:2:2. Output is the Luma of YUV4:2:0. RZX_RGB_EN is ignored. Must be used to rescale YUV4:2:0 data: Second/first pass
1	1	Input is YUV4:2:2. Output is YUV4:2:0. RZX_RGB_EN is ignored.

9.3.3.6.6.1 ISS ISP RSZ Operating Modes

The RSZ module offers two basic rescaling modes. These modes are not built-in but are particular configurations, which means that other hybrid modes can be programmed. The normal mode provides more flexibility (the rescale ratio granularity is smaller) than downscale mode, but downscale mode produces better image quality (averager performs anti-aliasing):

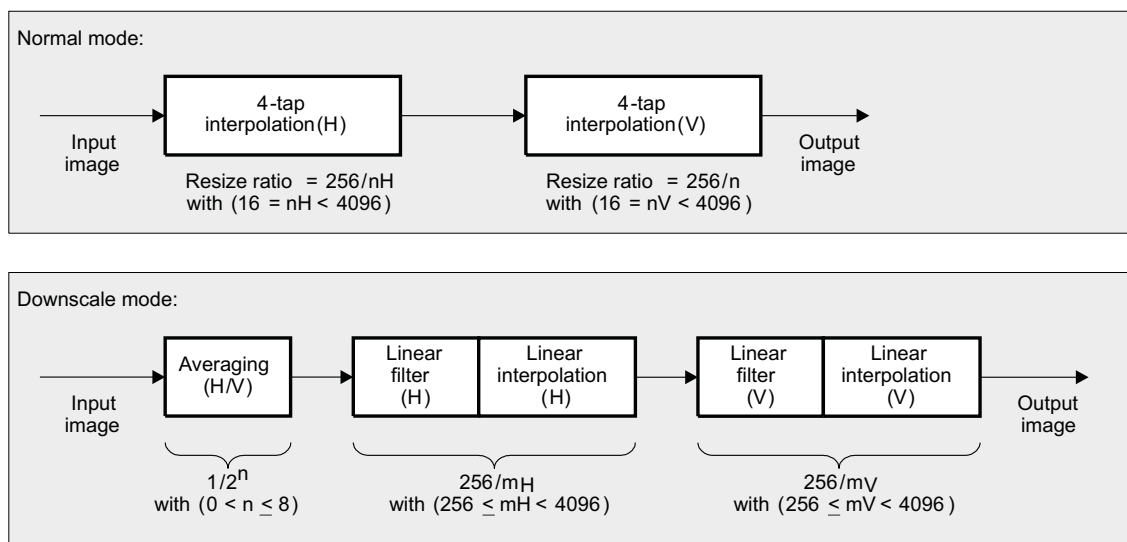

- Normal mode: The scaling process is carried out using interpolation with a 4-tap filter. The interpolation method is a 4-tap cubic convolution or a 3-tap linear filter + 2-tap linear interpolation. The user controls the type of interpolation that is used. The possible rescale ratios range from 1/16x to 20x.
- Downscale mode: The scaling process is the same as for normal mode, but an averaging function is placed before. It enables reaching much higher reduction factors while avoiding anti-aliasing artifacts. The interpolation method is a 4-tap cubic convolution or a 3-tap linear filter + 2-tap linear interpolation. The possible rescale ratios range from 1/4096x to 1x.

NOTE: The selection of the mode is independent for each resizer engine. One resizer engine can be configured in normal mode, while another is configured in downscale mode.

The RSZ module can produce two output images simultaneously, because there are two independent resizer engines. The input data used by the two resizer engines is the same. The RSZ output image sizes are limited to RSZ_GNC[12:0] RSZA_MEM_LINE_SIZE pixels/line for RSZ-A (2816 pixels/line) and RSZB_MEM_LINE_SIZE[28:16] for RSZ-B (3072 pixels/line).

Figure 9-96 shows the RSZ operating modes. Nothing prevents the use of linear interpolation in normal mode or bicubic interpolation in downscale mode; similarly, it is possible to mix the interpolation modes for horizontal and vertical filtering. This is fully programmable.

Figure 9-96. ISS ISP RSZ Operating Modes

camss-401

9.3.3.6.6.1 ISS ISP RSZ Operating Modes and Maximum Input Clock

The maximum output pixel clock on both resizers is 532 MHz (OPP_HIGH); that is, a pixel throughput of 532 MPix/s. Moreover, hardware takes care of the following constraints:

- When both resizer engines are configured to perform downscaling, there is no particular constraint on the VP pixel clock. The VP pixel clock can be as high as 532 MHz.
- When one resizer engine is configured to perform upscaling and the second resizer engine is configured to perform downscaling, the VP pixel clock must be limited. The VP must be lower than:

$$\text{clk_pix} \leq (532 \text{ MHz} / (\text{Vertical Upscale Ratio} \times \text{Horizontal Upscale Ratio})) \quad (2)$$

For example, if a 4x upscale ratio happens horizontally and vertically, then the input pixel clock must be lower than $532 / (4 \times 4) = 66.5$ MHz.

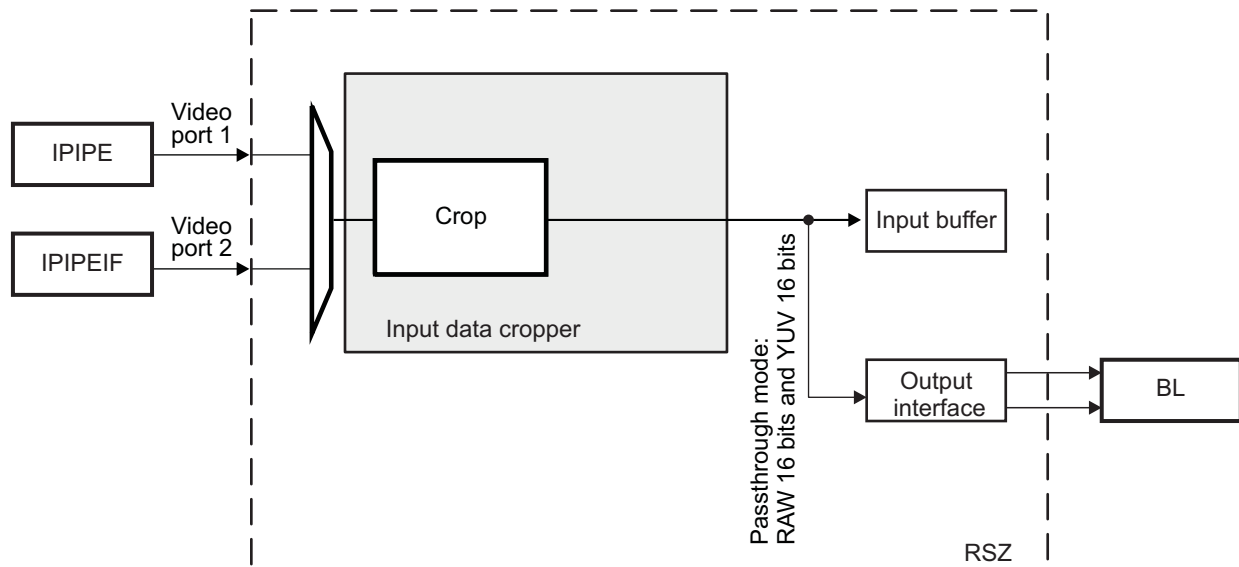

It is the reason why it is not possible to perform digital zoom upscaling on the fly. It is necessary to acquire the pixels to memory first and to read them back at a pace that does not exceed the previously discussed constraints. At the ISS level, data can be read back from memory by the CAL_B or ISIF module.

- When the two resizer engines are configured to perform upscaling, the VP pixel clock must be limited. In that case, the VP frequency is limited by the resizer engine having the larger rescale ratios.

9.3.3.6.6.2 ISS ISP RSZ Input Data Cropper

The data coming from the VPs into the RSZ module can be cropped: this applies to RAW and YUV4:2:2 data. It is mandatory to crop the data as early as possible in the RSZ processing pipeline to reduce power consumption. It is mandatory to crop the data before storing it in the input data buffer. [Figure 9-97](#) is the block diagram of the RSZ input data cropper.

Figure 9-97. ISS ISP RSZ Input Data Cropper Block Diagram

camss-708

The input data are in YUV4:2:2 interleaved format or RAW format.

For YUV4:2:2 format, the data come as Cb0, Y0, Cr0, Y1, Cb2, Y2, Cr2, Y3, etc. Y denotes the Luma component value and Cb/Cr denotes the Chroma component values. There are as many Y components as Cb/Cr components per line.

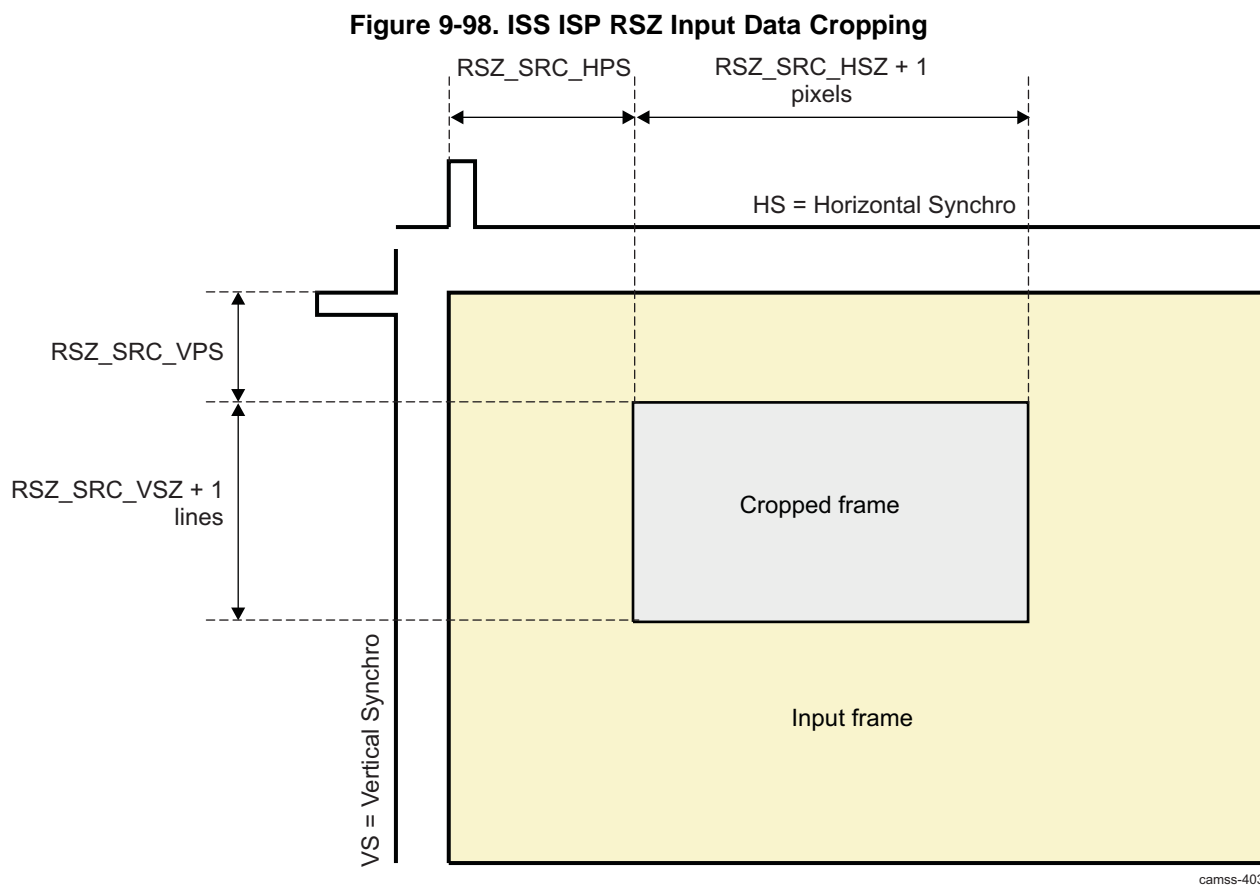

Figure 9-98 shows input data cropping. Only the cropped data is stored in the input data buffer. The names used in the figure correspond to the register names. If no cropping is desired, the `RSZ_SRC_HPS` and `RSZ_SRC_VPS` registers, which set the horizontal and vertical positions, respectively, must be set to 0; the start size from the `RSZ_SRC_HSZ` register must be set to the input image width minus 1, and the `RSZ_SRC_VSZ` register must be set to the input image height minus 1. These are common settings for both resize engines inside the RSZ module. After setting, more flexibility is present through the `RZx_i_VPS` and `RZx_i_HPS` registers for vertical and horizontal positioning, respectively, of the input/output (where $x = A$ or B , $i = I$ or O).

NOTE: After the RSZ second level cropping (defined by `RZA_I_VPS` and `RZB_I_VPS` register settings), the height of the image frame must be two lines or larger. A one-line image is not allowed.

Depending on the input data format, different constraints apply to the registers that set the cropping parameters:

- For YUV4:2:2 format, the vertical start positions of the cropped frame can be even or odd. However, the horizontal start position must be even: the reason is to always start with the same pattern: Cb_{2n} , Y_{2n} , Cr_{2n} , Y_{2n+1} , etc. For the same reason, the horizontal size of the cropped frame (`RSZ_SRC_HSZ + 1`) must be an even number. Finally, the vertical size of the cropped frame can be odd or even.
- For RAW format, the vertical start position of the cropped frame can be even or odd. The vertical size can be even or odd. The horizontal resolution must be even.

These features and constraints are common for both resizer engines inside the RSZ module. Figure 9-98 shows the input data cropping.

camss-403

9.3.3.6.6.3 ISS ISP RSZ Averager

9.3.3.6.6.3.1 ISS ISP RSZ Use Cases

The two resizer engines can have independent averager settings:

- Both resizers can use the averager.
- One resizer can bypass it and the other can use the averager.
- Both resizers can bypass the averager.

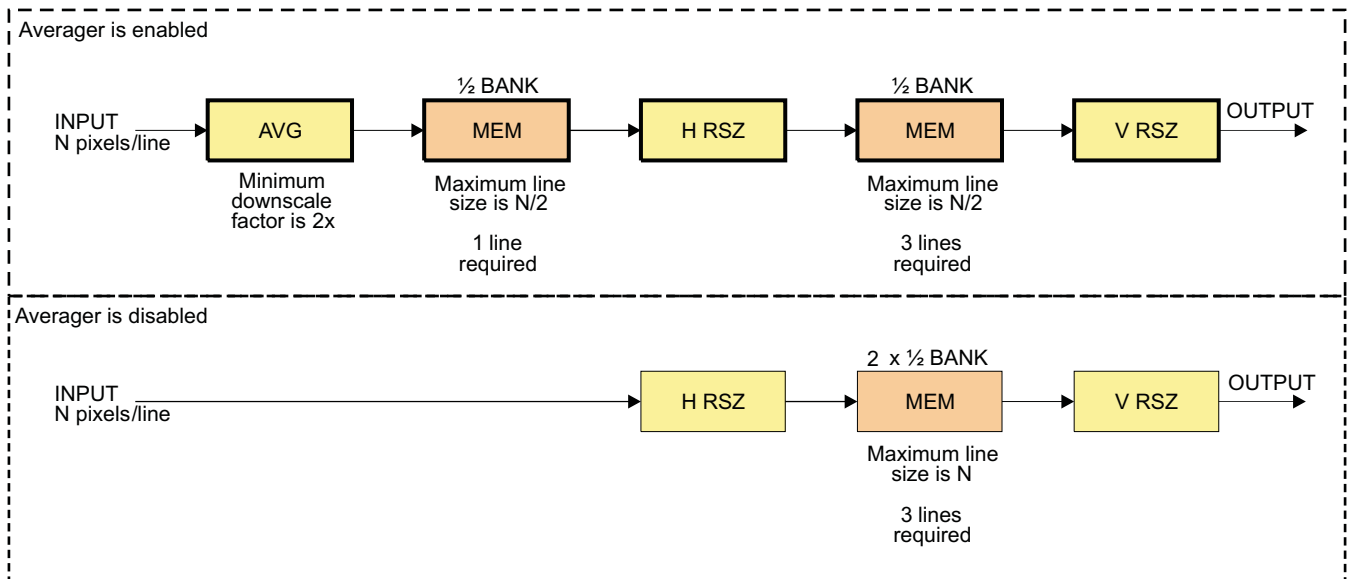

9.3.3.6.6.3.2 ISS ISP RSZ Memory Use

Vertical averaging requires memory to perform pixel data accumulation. It shares the vertical memory lines that are used for vertical filtering: this is the reason why the vertical memory lines are organized as two banks of half lines.

- The averagers output lines that are at most half the size of the input image in one memory bank.
- The horizontal resizers write their output data in the second memory banks.

Figure 9-99 shows the use of memory when the averager is enabled or disabled.

Figure 9-99. ISS ISP RSZ Averager Memory Utilization

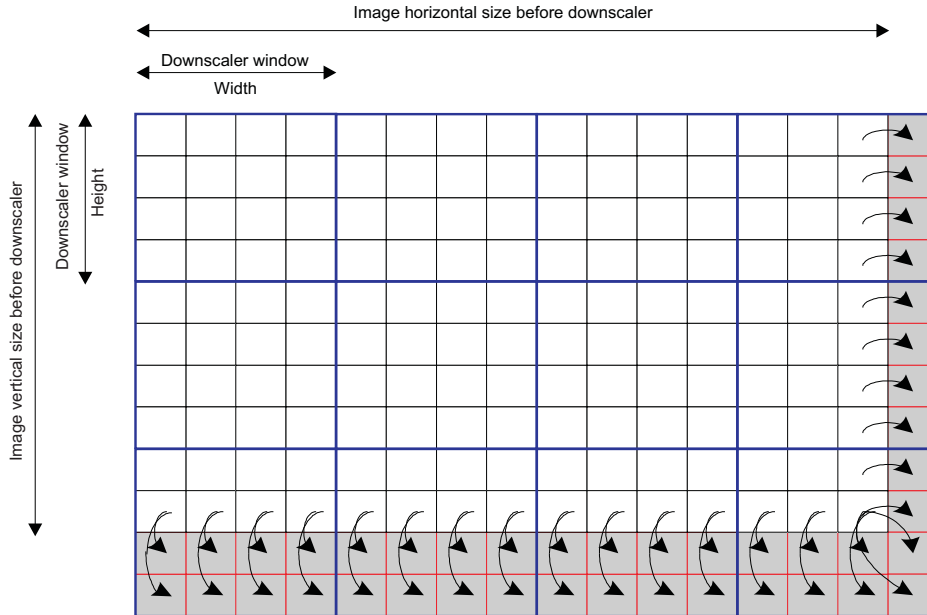

camss-407

9.3.3.6.6.3.3 ISS ISP RSZ Border Conditions

Figure 9-100 shows the averager behavior for border conditions. If the input image is not big enough, border duplication must occur.

Figure 9-100. ISS ISP RSZ Averager Border Conditions

camss-408

Downscaling is enabled from the RZi_DWN_EN register. Moreover, the vertical averaging size is set by the RZA_DWN_AV[5:3] V bit field. The actual downscale ratio is given by $1/2^{(RZA_DWN_AV[5:3] V + 1)}$. The range is from 1/2 to 1/256 in power of 2. The horizontal averaging size is set by the RZA_DWN_AV[0:2] H bit field. The actual downscale ratio is given by $1/2^{(RZA_DWN_AV[0:2] H + 1)}$. The equations are the same for RSZ-B. The range goes from 1/2 to 1/256 in power of 2.

9.3.3.6.6.4 ISS ISP RSZ Interpolation

Figure 9-101 shows the basic interpolation method used in the RSZ module. The following assumptions are made:

- The distance between each input pixel is 1.
- The magnification ration is given by $256/N$ and $p/256$ is the initial phase of the output data.

The output pixels are also evenly spaced. The distance between each output pixel is given by $N/256$. In the example in Figure 9-101, N is greater than 256. The position of the n^{th} output pixel is given by $(n \times N + p) / 256$.

Figure 9-101. ISS ISP RSZ Basic Interpolation Method

camss-682

Assuming the intensity of input pixels is i_0, i_1, i_2 , etc. and the resized (output) pixels are o_0, o_1, o_2 , etc., the n th output pixel (o_n) is determined using the nearest 4 input pixels as follows:

$$o_n = h(1 + d) \times i_m + h(d) \times i_{m+1} + h(d - 1) \times i_{m+2} + h(d - 2) \times i_{m+3}$$

In the previous equation $h(x)$ is the interpolation main function. The RSZ module supports linear and bicubic convolution interpolation functions.

Figure 9-102 shows the interpolation principle at the n th output pixel (o_n) at position x_n . Furthermore, the m and d parameters are as follows:

$$m = \text{floor}((n \times N + p) / 256) \text{ and } d = ((n \times N + p) / 256) - m$$

Figure 9-102. ISS ISP RSZ Interpolation Filtering

camss-683

For each resizer (RSZ-A or RSZ-B), and for Chroma and Luma, the interpolation method for vertical interpolation can be a 2-tap linear interpolation or a 4-tap cubic convolution (default) method. The choice is made in RZi_V_TYP[0] Y for Luma and RZi_V_TYP[1] C for Chroma, where i = A or B and is the resizer number. It is similar for horizontal interpolation from RZi_H_TYP[0] Y for Luma and RZi_H_TYP[1] C for Chroma, where i = A or B and is the resizer number.

9.3.3.6.6.4.1 ISS ISP RSZ Liner Interpolation Input Data

Before data interpolation, a low pass filtering (LPF) operation is required on the input data. The following equation gives the LPF function. The equation is evaluated at pixel position d_i but neighbor pixels d_{i-1} and d_{i+1} are required. The gain value g is set up by the register RZi_V_LPF and RZi_H_LPF. Different gains are possible horizontally and vertically as well as for Luma and Chroma.

$$LPF_g(d_{i-1}, d_i, d_{i+1}) = d_i + g \times (d_{i-1} - 2d_{i+1} + d_{i+2})/128$$

9.3.3.6.6.4.1.1 ISS ISP RSZ Cubic Convolution Mode

The input data is not modified in bicubic mode. The input is equal to the output.

9.3.3.6.6.4.1.2 ISS ISP RSZ Phase Settings

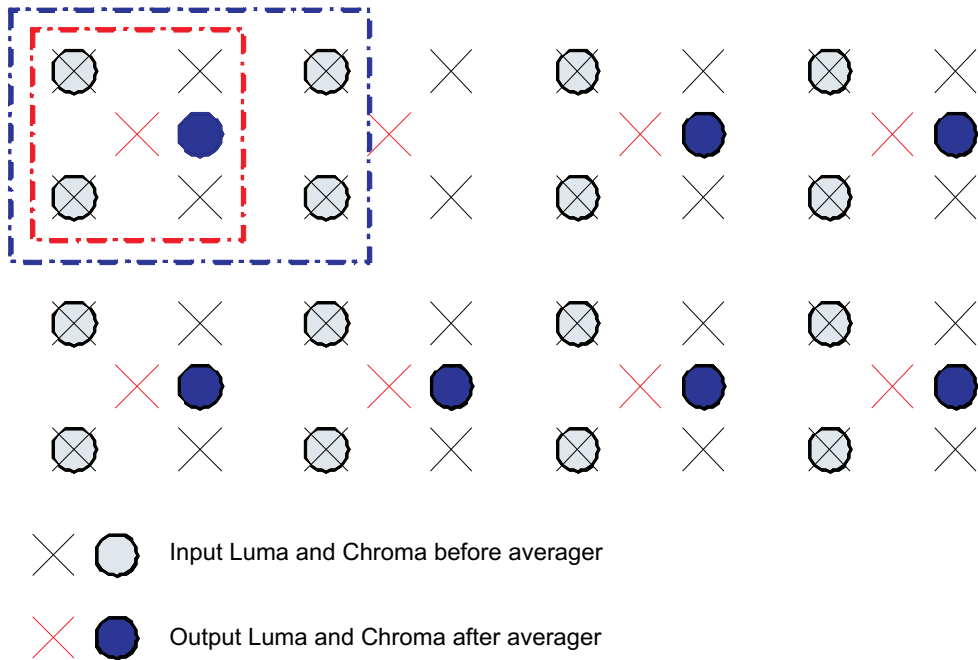

The initial value for the phase value for vertical resizing is set by the RZi_V_PHS_Y for Luma and RZi_V_PHS_C for Chroma. These values are in the U14Q8 fractional format (values in the range [0 – 63.996]). When YUV4:2:2 data are output, the phase value for Luma and Chroma must be aligned; that is, RZi_V_PHS_Y = RZi_V_PHS_C.

The following constraint equation applies: $|RZi_V_PHS_Y - RZx_V_PHS_C| \leq RZi_V_DIF$. This constraint means that at most the distance between the initial phases for Luma and Chroma is not expected to exceed the distance between two Luma pixels. The absolute value is used; therefore, the initial Luma phase can be greater than the initial Chroma phase or vice versa. As a reminder, the distance between two output pixels for Luma is given by RZi_V_DIF.

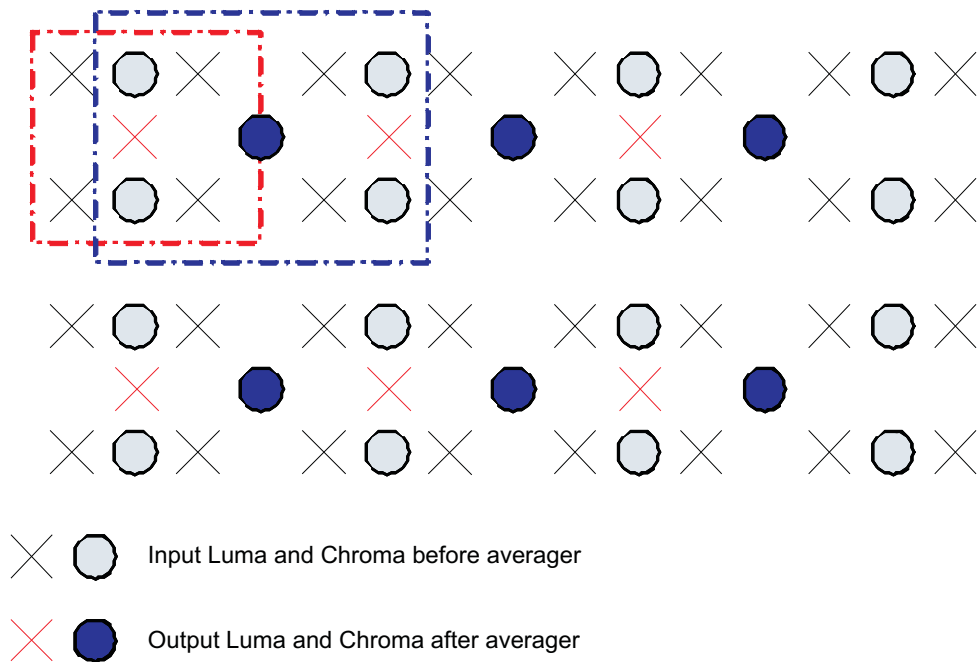

The initial value for the phase value for horizontal resizing is set by the RZi_H_PHS register. The RZi_H_PHS_ADJ register enables adjusting the horizontal phase for the Luma component when averaging is enabled (the averager disrupts the relative sampling point between Luma and Chroma when YUV4:2:2 co-sited data is input). The relative phase between Luma and Chroma is different before and after the horizontal averager. The vertical phase is not affected by the averager. [Figure 9-103](#) shows the effect of the averager on the phases. RZi_H_PHS_ADJ is expected to be equal to 0 if the averager is disabled.

Figure 9-103. ISS ISP RSZ-A/RSZ-B Phase Averager Effect

Input Chroma is co-sited: relative input I/O phases btw Y and UV are different, correction is needed.

Input Chroma is centered: relative input I/O phases btw Y and UV are identical, no correction is needed.

camss-685

9.3.3.6.6.5 ISS ISP RSZ Data Saturator

After vertical rescaling and before color conversion, the output data is saturated (clipped) to programmable values that are given by the following registers:

- [RSZ_YUV_Y_MIN](#)
- [RSZ_YUV_Y_MAX](#)
- [RSZ_YUV_C_MIN](#)
- [RSZ_YUV_C_MAX](#)

The maximum Y value is set up with the [RSZ_YUV_Y_MAX](#) register. If the input Y value is greater than the MAX value, it is clipped to MAX.

The minimum Y value is set up with the [RSZ_YUV_Y_MIN](#) register. If the input Y value is smaller than the MIN value, it is clipped to MIN.

The maximum Cb/Cr value is set up with the [RSZ_YUV_C_MAX](#) register. If the input Cb/Cr value is greater than the MAX value, it is clipped to MAX.

The minimum Cb/Cr value is set up with the [RSZ_YUV_C_MIN](#) register. If the input Cb/Cr value is smaller than the MIN value, it is clipped to MIN.

9.3.3.6.6 ISS ISP RSZ Color Converter

As mentioned previously, the resizer can support RAW, YUV4:2:0, and YUV4:2:2 formats. The resizer engines can also support RGB output: RGB5:6:5 and ARGB32.

The RGB5:6:5 data is 16 bits wide and consists of 5 bits for red, 6 bits for green, and 5 bits for blue.

The following table shows the way RGB5:6:5 is stored to memory. This data format is compatible with the display controller. Only the little-endian memory representation is supported.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R1					G1						B1					R0				G0			B0								

The ARGB32 data is 32 bits wide and consists of 8 bits for alpha, 8 bits for red, 8 bits for green, and 8 bits for blue. The alpha value is global and is set for the entire frame; registers control the alpha value: the RZx_RGB_BLD register controls the alpha values of resizer A and resizer B.

The following table shows the way ARGB32 is stored to memory. This data format is compatible with the display controller. This representation is endianness invariant: it is the same for little endian and big endian.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
A								R								G								B							

The RGB output is enabled by setting the RZx_RGB_EN[0] RGB_EN bit to 1.

The RGB format is set by the RZx_RGB_TYP[0] TYP bit (0 for ARGB32 format and 1 for RGB5:6:5).

To handle the horizontal border conditions, the left-most Chroma sample or the right-most Chroma sample is duplicated on the left or the right.

Software must make it possible to remove 2 pixels on the left and/or right to take care of the issues that Chroma duplication introduces on the borders. The RZx_RGB_TYP[1] MSK0 and RZx_RGB_TYP[2] MSK1 bits control this feature.

[Figure 9-104](#) shows the ISS ISP RSZ chroma position and upsampling.

Figure 9-104. ISS ISP RSZ Chroma Position and Upsampling

NOTE: In case Cb/Cr in the input image is flipped, the `RSZ_SRC_FMT1[3] CHR` bit must be set to 1 to assure correct color conversion. This setting restores the right order in YUV to RGB conversion, and generates correct RGB colors.

9.3.3.6.6.7 ISS ISP RSZ Output Interface

The output interface receives the data generated by the two resizer engines and generates the addresses and the port requests to the BL module.

- The port 1 interface is dedicated to the RSZ-A module. If the RSZ module is set up in pass-through mode, then the data is output on the port 1 interface. This interface can transfer RAW, YUV4:2:2, YUV4:2:0, and RGB data
- The port 2 interface is dedicated to the RSZ-B module. This interface can transfer RAW, YUV4:2:2, YUV4:2:0, and RGB data.

The YUV4:2:0 data format is handled differently from the other formats because the output data are written at two different memory locations: Luma in one buffer and Chroma in a second buffer. For all other formats the data are written in the same buffer.

Each data format must be stored in memory in a dedicated manner, which is summarized in [Table 9-223](#).

Table 9-223. ISS ISP RSZ Output Interface: Data Formats

Output Format	Bytes per Pixel	Output Buffers per Image	Interface Supporting the Data Format
RAW	2	1	MTC port 1
YUV4:2:2	2 average	1	MTC port 1 port 2
YUV4:2:0	1.5 average	2	MTC port 1 port 2
RGB16	2	1	MTC port 1 port 2
ARGB32	4	1	MTC port 1 port 2

9.3.3.6.6.7.1 ISS ISP RSZ Circular Buffer

Figure 9-105 shows the parameters that are required to set up the circular buffers. As mentioned previously, there can be up to four circular buffers in case the two resizer engines are outputting YUV4:2:0 data.

The circular buffer management requires the following parameters (RSZ-A or RSZ-B A or B, Chroma or Luma Y or C, low or high part of the address, L or H. Sets the base address of the circular buffer):

- Baseline address (BAD, in registers, where x is the resizer A or B, and i is Y or C)
- Start address (SAD, in RZx_SDR_i_SAD_j registers)
- Start pointer (PTR_S, in RZx_SDR_i_PTR_S registers)
- End pointer (PTR_E, in RZx_SDR_i_PTR_E registers)
- Line offset (OFT, in RZx_SDR_i_OFT registers)

Table 9-224. ISS ISP RSZ Circular Buffer

Circular Buffer Parameter	Register (for RSZ-A and RSZ-B)	Description
Baseline address	RZA_SDR_Y_BAD_H RZA_SDR_Y_BAD_L RZA_SDR_C_BAD_H RZA_SDR_C_BAD_L RZB_SDR_Y_BAD_H RZB_SDR_Y_BAD_L RZB_SDR_C_BAD_H RZB_SDR_C_BAD_L	Sets the base address of the circular buffer
Start address	RZA_SDR_Y_SAD_H RZA_SDR_Y_SAD_L RZA_SDR_C_SAD_H RZA_SDR_C_SAD_L RZB_SDR_Y_SAD_H RZB_SDR_Y_SAD_L RZB_SDR_C_SAD_H RZB_SDR_C_SAD_L	Sets the start address of the circular buffer. The first data output is written to this address. If the first line of a frame must be written at the beginning of the circular buffer memory, then $SAD = BAD$ and $PTR_S = 0$.
Start pointer	RZA_SDR_Y_PTR_S RZA_SDR_C_PTR_S RZB_SDR_Y_PTR_S RZB_SDR_C_PTR_S	Sets the initial value of the circular buffer internal counter. It must be set up as $PTR_S = (SAD - BAD)/OFT$. PTR_S is expressed in the number of lines.
End pointer	RZA_SDR_Y_PTR_E RZA_SDR_C_PTR_E RZB_SDR_Y_PTR_E RZB_SDR_C_PTR_E	Sets the size of the circular buffer. PTR_E is expressed in the number of lines. The circular buffer can contain up to PTR_E lines.
Line offset	RZA_SDR_Y_OFT RZA_SDR_C_OFT RZB_SDR_Y_OFT RZB_SDR_C_OFT	This is the offset expressed in bytes between two lines in the circular buffer. Here: Line 0 = SAD, Line 1 = SAD + 1 × OFT, Line 2 = SAD + 2 × OFT, etc. OFT does not necessarily correspond to the size of a line in a frame; it can be bigger.

More generally, the following equations hold:

- $SAD = BAD + (PTR_S \times OFT)$ and $PTR_S < PTR_E$

Interrupts can be triggered every time a certain number of lines are written to the circular buffer. There are independent settings for each RSZ and for each possible output of each RSZ.

Figure 9-105. ISS ISP RSZ and Circular Buffer Settings

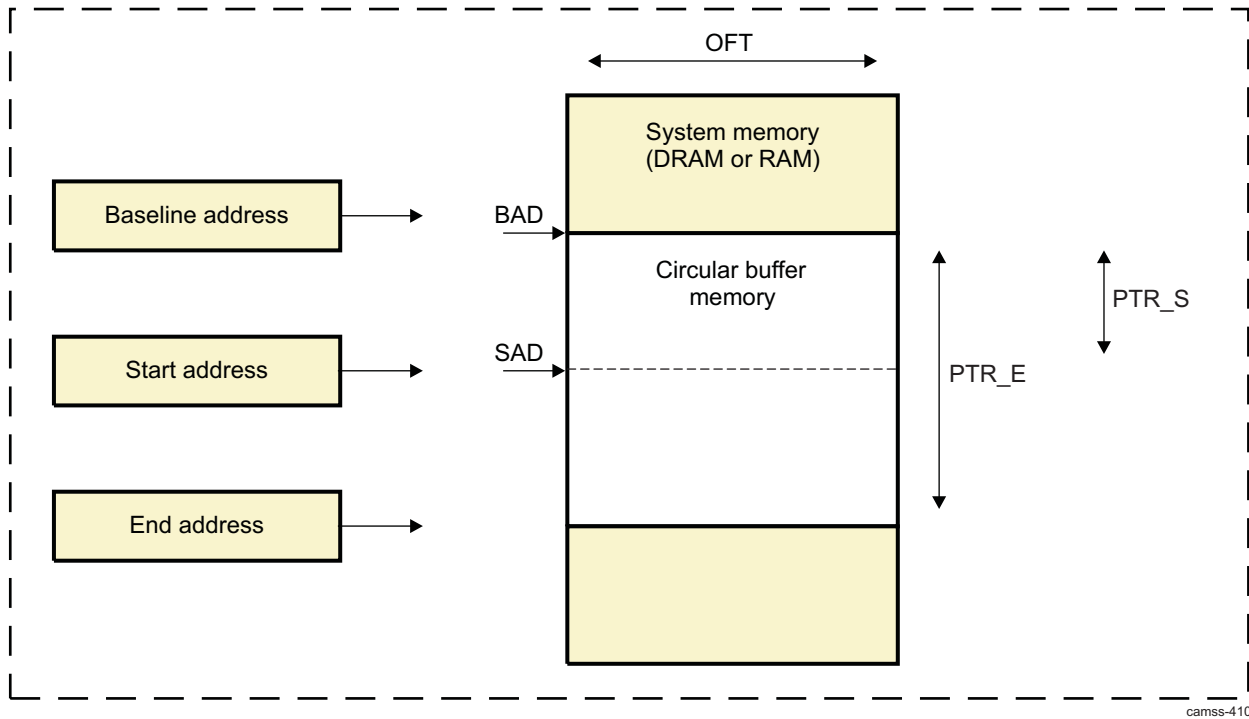

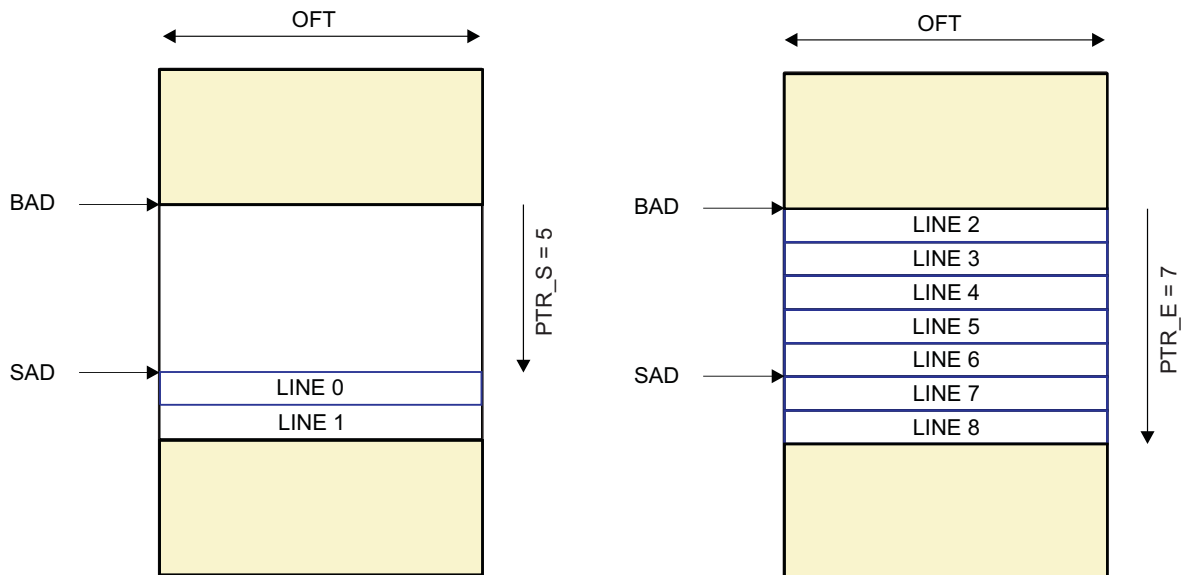

Figure 9-106 shows how the data are stored in the circular buffer over time when vertical flip is disabled. In this example, PTR_S = 5 and PTR_E = 7. There can be up to PTR_E = 7 lines in the circular buffer.

Figure 9-106. ISS ISP RSZ and Circular Buffer Settings – Example 1

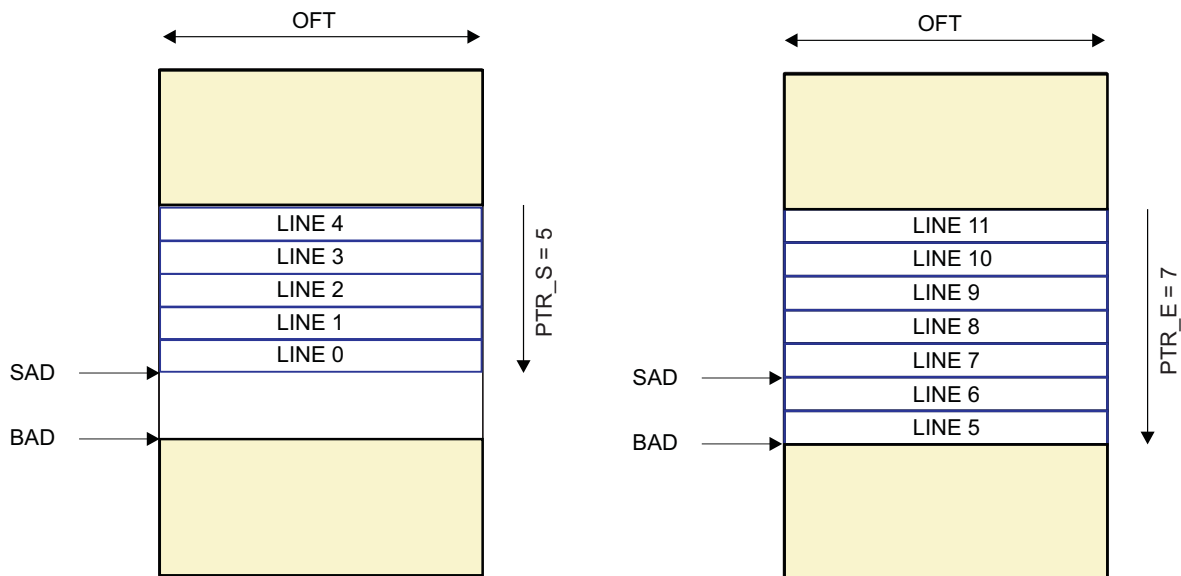

Vertical flip enabled:

1. Start from SAD.
2. Output PTR_E – PTR_S lines.
3. Wrap to BAD.
4. Output PTR_E lines and continue wrapping to BAD.

camss-412

Figure 9-107 shows how the data are stored in the circular buffer over time when vertical flip is enabled. In this example, PTR_S = 5 and PTR_E = 7. There can be up to PTR_E = 7 lines in the circular buffer.

Figure 9-107. ISS ISP RSZ and Circular Buffer Settings – Example 2

Vertical flip enabled:

1. Start from SAD.
2. Output PTR_E – PTR_S lines.
3. Wrap to BAD.
4. Output PTR_E lines and continue wrapping to BAD.

camss-413

9.3.3.7 ISS ISP CNF Functional Description

9.3.3.7.1 ISS ISP CNF Overview

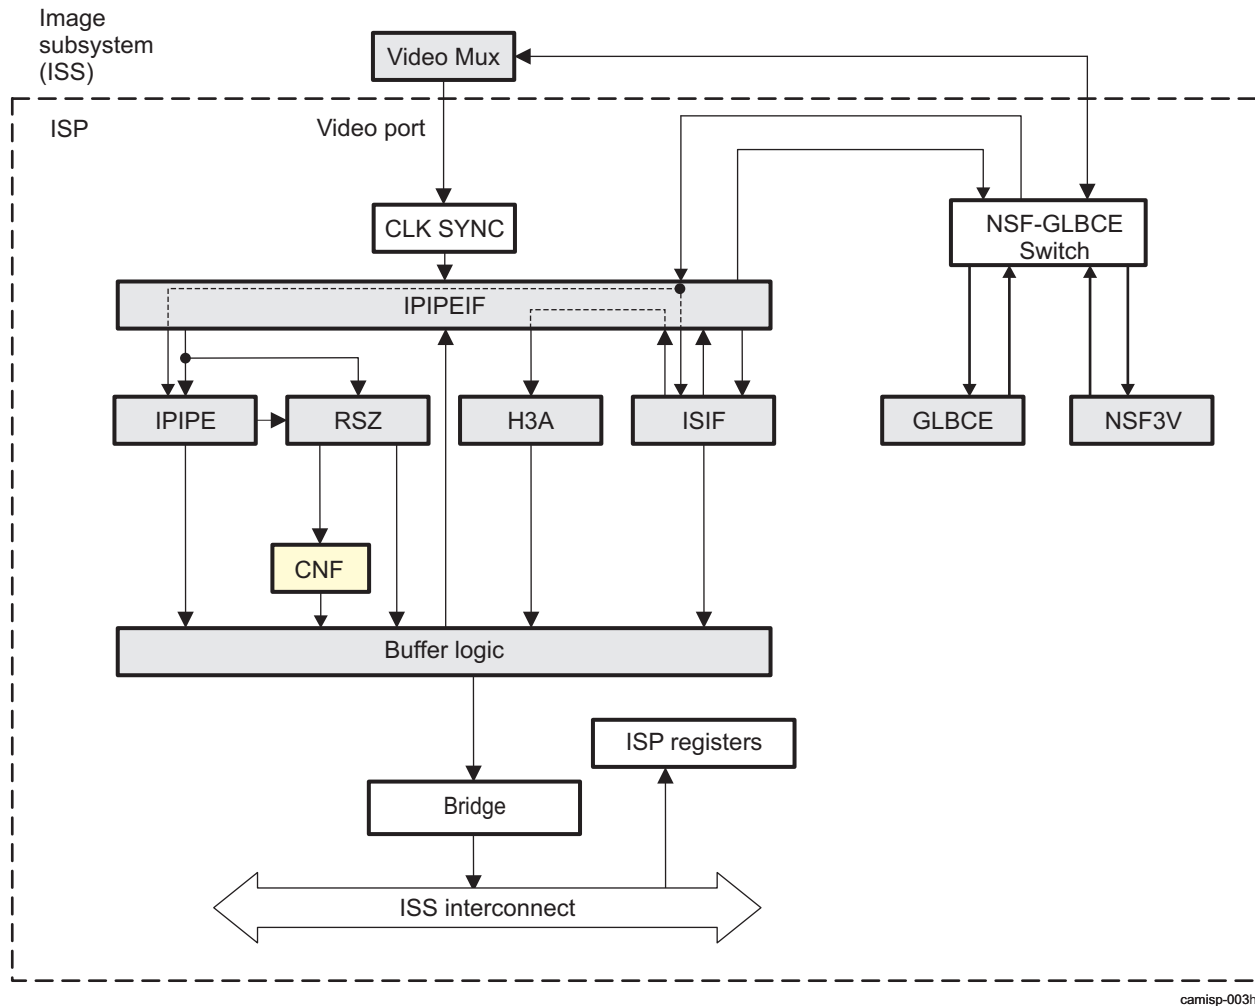

CNF removes residual chroma noise (color variation seen in dark area of low light images. Usually in low frequency) by filtering UV data component of the image with noise filter. CNF is resided beside RSZ, and takes in UV and gives them back to RSZ.

CNF works with RSZ, and filters noises in chroma (UV or Cb/Cr) channel. CNF filters UV part of YUV420 image data. CNF only works on YUV420-UV, YUV420-YUV. It does not support YUV422 and YUV420-Y. One (CNFA) is attached to RSZ-A. CNFA supports up to 2816 pixels/line. The core of CNF is based on NSF3V UV processing. The functions of CNF are

- Noise filter, which uses the same core as NSF3V UV filter
- Advanced threshold control inherited from NSF3V
- On-the-fly processing without round trip to external memories
- x1/2 chroma down sampling and x2 chroma upsampling
- Works only on YUV-420
- CNF module works with the line width supported by the RSZ1 output.
- Top/bottom border pixels are always replicated to maintain the size of the output
- Left/Right border pixels replication may be turned on or off. By turning on the replication, the output size is same as input. By turning off, frame division mode stitching is supported.
- Provide chroma noise filtering necessary for low-light images and video.
- Optionally noise-filter downsampled chroma to provide additional level of noise reduction.

Figure 9-108 show the CNF module connections to other submodules of the ISP.

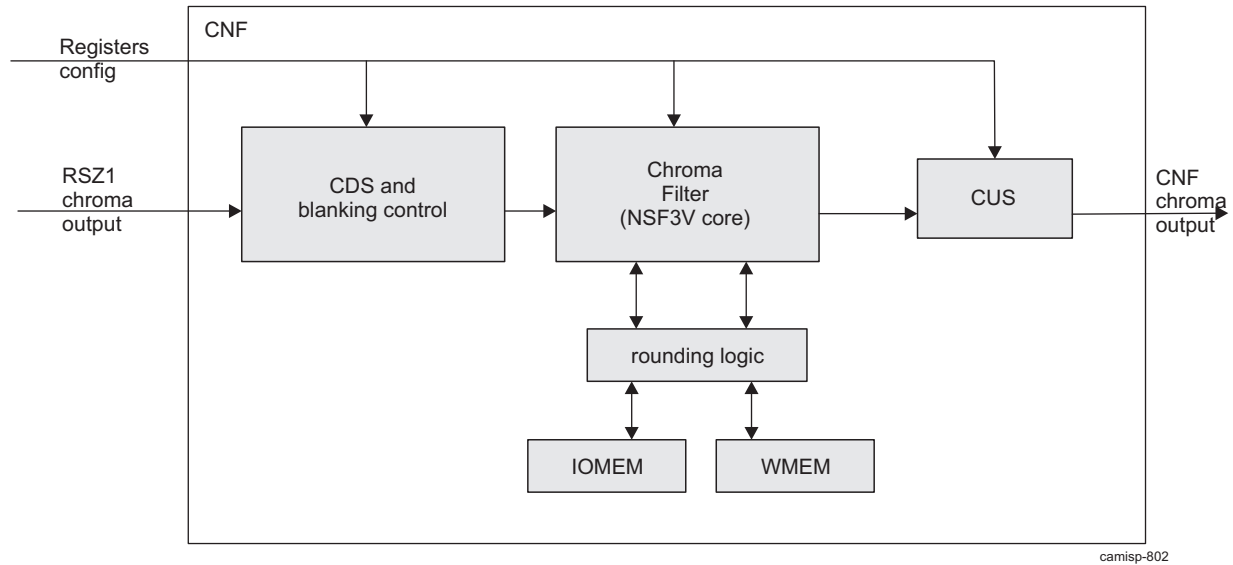

Figure 9-108. ISS ISP CNF High-Level Diagram

9.3.3.7.2 ISS ISP CNF Top Level Block Diagram

Figure 9-109 is the top-level block diagram of the CNF module. The RSZ module comprises the following submodules: cropping, input data buffering, data requestor, averager, data saturation, and resizer interpolation (comprised of horizontal rescaler, vertical rescaler, color conversion, and output interface) (see the following sections for more information).

Figure 9-109. ISS ISP CNF Top Level Block Diagram

NOTE: Although CNF does not generate horizontal blanking violation error interrupts. This is because CDS module will always generate enough blanking. Instead, inadequate number of horizontal blanking cycles will eventually generate back pressure to RSZ1 input buffer, and will cause buffer over flow if the upstream receiver module can not be stalled.

9.3.3.7.3 ISS ISP CNF Noise Filter Algorithm

The CNF module integrates an NSF3V instance. The CNF block contains chroma downsampling and upsampling blocks before and after the NSF3V instance. See [Section 9.3.3.3](#) for details on NSF3V functionality and noise filter algorithm.

9.3.3.7.4 ISS ISP CNF Chroma Downsampling and Upsampling

When configured CDS-on (`ISP_CNFA_EN[0] CNFA_EN`), chroma is downsampled before the chroma filter core, and upsampled after the chroma filter core.

For downsampling, a simple 2x2 non-overlapping averaging scheme is used. For upsampling, overlapping bilinear interpolation is used. [Figure 9-110](#) shows the spatial relationship between the original and downsampled data points, and the downsampling/upsampling schemes.

Figure 9-110. ISS ISP CNF original and downsampled grid, and downsample/upsample schemes

NOTE: Chroma downsampling/upsampling is performed outside the chroma filter core (NSF3V reuse), so the core is not aware of the downsampling option. When CDS-on, the core should be programmed with half the width and height, as that's the size of the image the core is receiving and producing.

As chroma downsampling utilizes non-overlapping 2x2 averaging, no special border treatment is needed. Chroma upsampling, however, utilizes overlapping bilinear interpolation, and border treatment is needed. The left/right/top/bottom data points are replicated to produce the missing border data needed, as shown in the [Figure 9-111](#)

Figure 9-111. ISS ISP CNF Chroma upsampling border replication scheme

NOTE: This is just the algorithm specification, and does not imply that the hardware implementation literally replicate border data points this way; hardware implementation seek to produce the equivalent outcome efficiently.

9.3.3.7.5 ISS ISP CNF Vertical and Horizontal Blanking

CNF, by instantiating NSF3V, inherits NSF3V vertical and horizontal blanking requirements. In YUV420UV mode with all border replication enabled, minimal horizontal blanking is 58 pixels, and minimal vertical blanking is 9 lines.

Note that:

- Horizontal blanking is not additional pixels or data points, but is the additional clock cycles required. As the chroma filter core operates at divided-by-2 clock, there is a 2x multiplier in number of functional clock cycles
- For example, when $IW = 1920$, there is 1920 data points per line (U and V together), so time between first data point of each line should be $(1920 + 52) * 2$ functional clock cycles.
- Vertical blanking is counted as number of dummy (data don't care) lines in the input.
- CDS block takes care of providing sufficient vertical and horizontal blanking.

CNF's downstream module, MTC interface, may occasionally negate `rsz_out_rdy` to suspend CNF sending pixel output, and this suspension may lead to `vpout_suspend` being asserted to the chroma filter core, and this may or may not lead to `vpin_suspend` being asserted by the chroma filter core, due to the FIFO mechanism inside the chroma filter core. In order to maintain sufficient HS interval to the chroma filter core, the CDS block needs to delay sending `VPin_HS` until

- `VPin_HE` is asserted by CDS block (all input pixels delivered) followed by `T_input_pipeline_delay`.
- `VPout_HE` is asserted by the chroma filter core (all output pixels delivered).
- Datapath processing time is met or $image_width + dp_pipeline_delay$ cycles under the specific mode and left/right border replication condition CNF operates in.

Refer to [Section 9.3.3.3](#) for specific delay cycle counts.

9.3.3.7.6 ISS ISP CNF configuring ranges/restrictions

As CNF is reusing NSF3V logic for the core functionality, most of the programming model follows that of NSF3V (see [Section 9.3.3.3.3](#)).

NSF3V in YUV420UV mode has the following constraints:

- Register (luma) image width multiple of 4.
- Register (luma) Image height multiple of 2.
- Minimal (luma) output width of 64, and since border replication is enabled, this directly applies to (luma) input width
- Minimal (luma) output height of 2, and since border replication is enabled, this directly applies to (luma) input height.

When the optional chroma downsampling is enabled, the CNF core gets half of the width and half of the height. In addition, CDS/CUS stages need to work with downsampled chroma having minimal height of 2 lines.

- Resizer output (luma) image width multiple of 8.
- Resizer output (luma) Image height multiple of 4.
- Resizer output (luma) minimal width of 128.
- Resizer output (luma) minimal height of 8 (thus chroma minimal height of 4, downsampled to 2)

In addition, the following constraints exist:

- Mode of operation is limited to YUV420UV (no interleaved YUV420UV either)
- Border replication, all 4 borders, are enabled
- Software reset is not supported.

NOTE: The image width/height programmed in the ISP-top level is to be consistent with the image width/height programmed in the CNF-core (NSF3V reuse) register space, and should be 1/2 of the resizer output when CDS is enabled. [Table 9-225](#) shows some example configurations.

Table 9-225. ISS ISP CNF CNF image width/height configuration examples

Resizer output width	Resizer output height	CDS	ISP-top CNF image width = CNF-core image width	ISP-top CNF image width = CNF-core image width	CNF input/output U/V data points
1920	1080	OFF	1920	1080	960 x 540 x 2
1920	1080	ON	960	540	480 x 270 x 2

The following NSF3V features are to be preserved:

- Radial shading gain
- Soft thresholding
- Edge enhancement
- Desaturation
- Output pixel clock
- One-shot and video mode
- Register shadowing

9.3.3.8 ISS ISP H3A Functional Description

9.3.3.8.1 ISS ISP H3A Overview

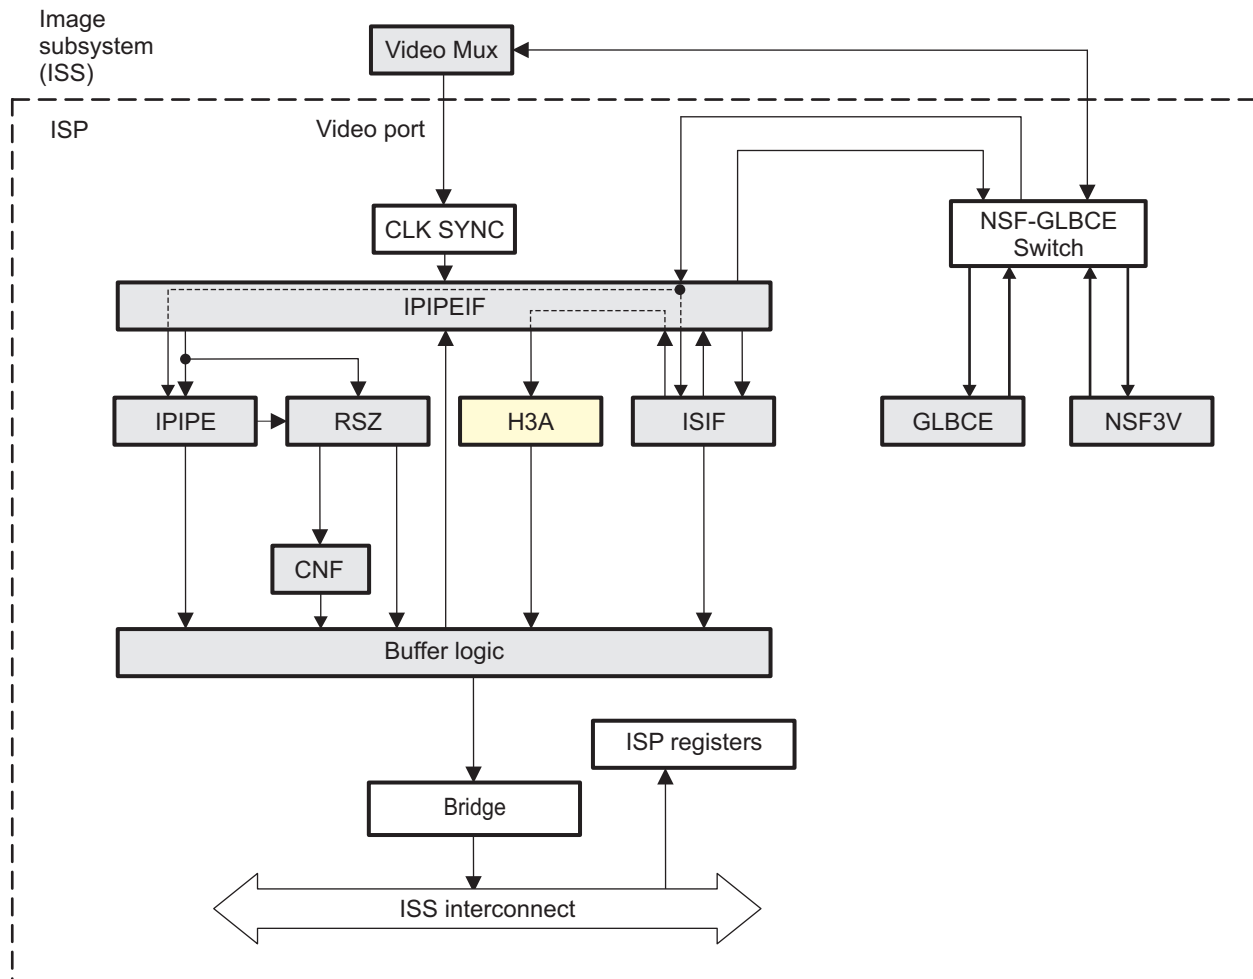

The H3A module supports the control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus (AF) engine:
 - The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a 2D block of data referred to as a paxel. The AF engine supports the following features:
 - Peak mode in a paxel: Accumulation of the maximum focus value (FV) of each line in a paxel
 - Accumulation mode in a paxel
 - Accumulation of horizontal and vertical focus value in a paxel
 - Up to 12 paxels in the horizontal direction and up to 12 paxels in the vertical direction with vertical focus
 - Up to 36 paxels in the horizontal direction and up to 128 paxels in the vertical direction with horizontal focus only
 - Programmable width and height for the paxel/window
 - Programmable red, green, and blue position within a 2 x 2 matrix
 - Separate horizontal start for paxel and filtering
 - Programmable vertical and horizontal line increments within a paxel
 - Horizontal FV uses parallel infinite impulse response (IIR) filters configured in a dual-biquad configuration with individual coefficients (two filters with 11 coefficients each). The filters are intended to compute the sharpness/peaks in the frame on which to focus.
 - Vertical FV uses a 5-tap FIR filter with 8-bit coefficients. With horizontal steps each paxel has up to 32 columns to be maintained for vertical FV calculation.
- Auto exposure and auto white balance (AE/AWB) engine:
 - The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the

video data. In the case of the AE/AWB, the 2D block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

- Accumulate clipped pixels along with all nonsaturated pixels in each window per color
- Accumulate the sum of squared pixels in each window per color
- Minimum and maximum pixel values in each window per color
- Support for up to 36 horizontal windows with sum + { sum_sq or min+max} output
- Support for up to 56 horizontal windows with sum output
- Support for up to 128 vertical windows
- Programmable width and height for the windows. All windows in the frame are the same size.
- Separate vertical start coordinate and height for a black row of paxels that is different than the remaining color paxels
- Programmable horizontal sampling points in a window
- Programmable vertical sampling points in a window
- Maximum pixel throughput of 532 MPix/s
- Double-buffer for paxel/window accumulation
- H3A data path is 10 bits.
- Maximum input size is 2816 pixels.

[Figure 9-112](#) shows the H3A module connections to other submodules of the ISP.

Figure 9-112. ISS ISP H3A High-Level Diagram

camisp-003b

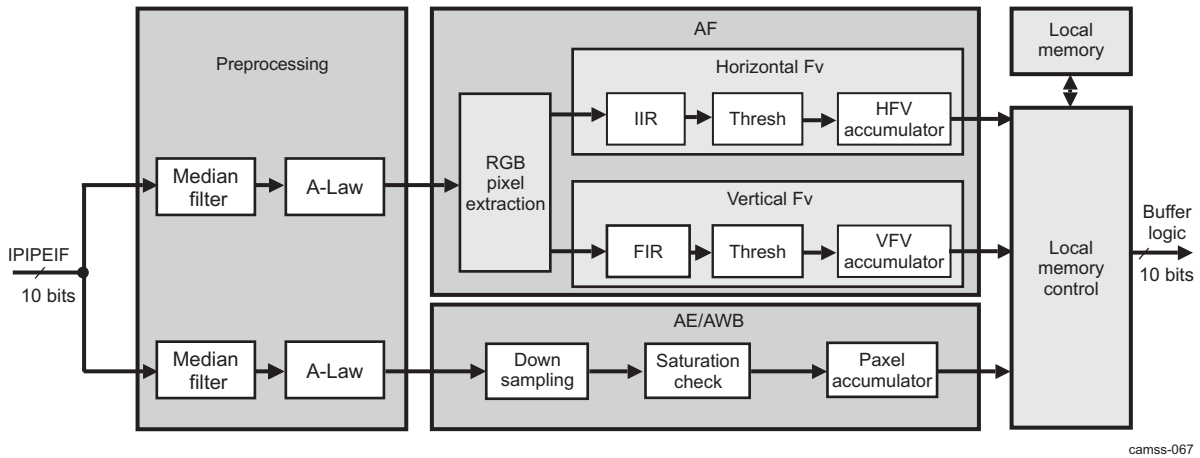

9.3.3.8.2 ISS ISP H3A Top-Level Block Diagram

The block diagram in [Figure 9-113](#) shows the process of the AF and AE/AWB data paths through the H3A module.

The data flow before H3A is:

1. Data comes from the VP or BL.
2. The data is processed by the ISIF.
3. The data is processed by the IPIPEIF.
4. The data is 10 bits from the IPIPEIF at H3A input.

Figure 9-113. ISS ISP H3A Top-Level Block Diagram

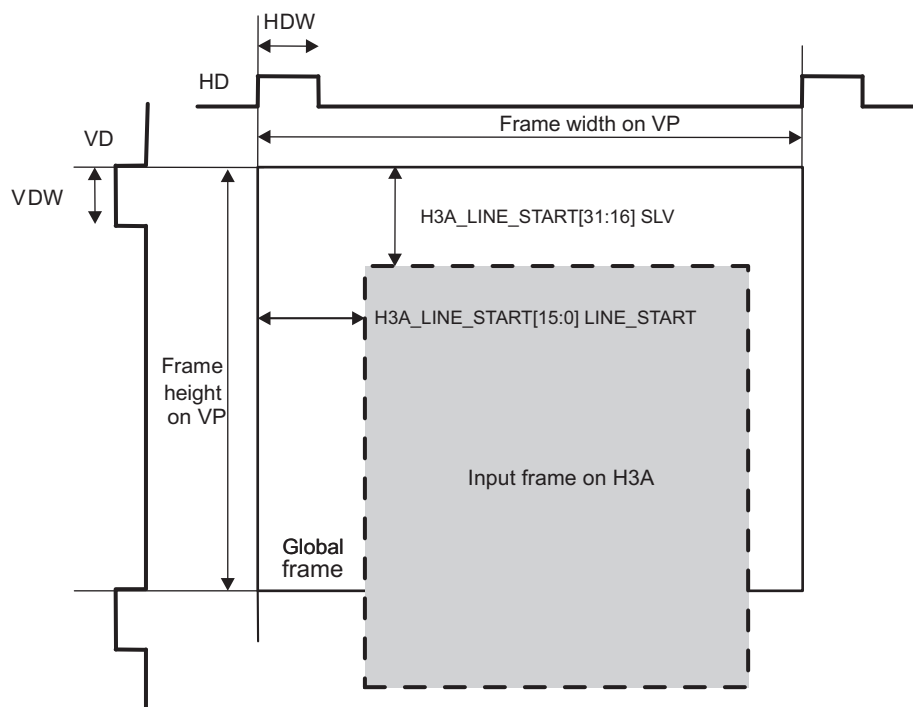

camss-067

9.3.3.8.3 ISS ISP H3A Line Framing Logic

In certain cases the number of clock cycles between HD pulses is greater than the line buffer included in the H3A. To solve this problem a framing module was added before the line buffer. The framing module uses the [H3A_LINE_START](#) register to find the position of the first pixel to place into the line buffer. All other registers reference this point as the 0 pixel for their start positions. The line size is 2816 pixels. After 2816 clock cycles the framing logic disables the line buffer and waits until the next HD. If the next HD comes before 2816 clock cycles, then the active region ends immediately and the counter waits for the [H3A_LINE_START](#) register count to be reached again. For the vertical position the [H3A_LINE_START\[31:16\]](#) SLV bit field can be used to determine where the start point of the frame is relative to the rising edge of VD. This logic allows for an active frame to cross VD boundaries and remain in the same frame.

Figure 9-114 shows the ISS ISP H3A frame format settings.

Figure 9-114. ISS ISP H3A Frame Format Settings

camisp-073

NOTE: (Frame width on VP) - (H3A_LINE_START[15:0] LINE_START) must be less than or equal to 2816, because the H3A memory lines are limited to 2816 pixels.

9.3.3.8.4 ISS ISP H3A Optional Preprocessing

The input to the H3A module is 10-bit RAW data from the IPIPEIF. A 10-bit to 8-bit A-Law compression step can be enabled and disabled separately for the AF engine (the H3A_PCR[1] AF_ALAW_EN bit) and the AE/AWB engine (the H3A_PCR[17] AEW_ALAW_EN bit). A-Law compression offers added protection against overflowing the accumulators.

If the A-Law table is enabled, the output is 10 bits, with the upper two bits filled with 0.

For the AF process, a horizontal median filter can be enabled and disabled (the H3A_PCR[2] AF_MED_EN bit) before A-Law compression. This filter is useful for reducing temperature-induced noise. The horizontal median filter calculates the absolute difference between the current pixel (i) and pixel (i - 2), and between the current pixel (i) and pixel (i + 2). If the absolute difference exceeds a threshold, and the sign of the differences is the same, the average of pixel (i - 2) and pixel (i + 2) replaces pixel (i). The threshold of the horizontal median filter can be set in the H3A_PCR[10:3] MED_TH bit field.

9.3.3.8.5 ISS ISP H3A Autofocus Engine

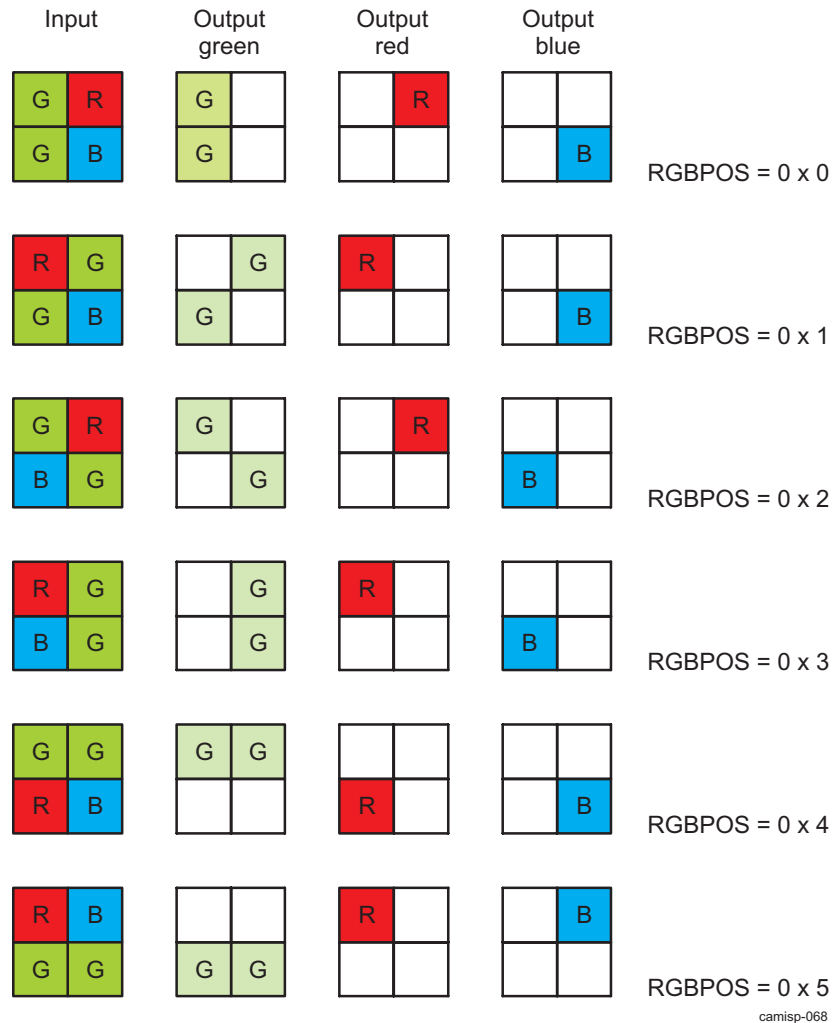

The AF engine works by extracting each green (Gr or Gb) pixel from the video stream and subtracts a fixed offset of 128 or 512 (depending of whether A-Law is enabled or disabled) from the pixel value. The offset value is then passed through an IIR filter and the absolute value of the filter output is the focus value (FV). Both FV and FV² are produced. The FV and FV² values can be accumulated or the maximum for each line/column can be accumulated. The following sections describe this process in more detail.

9.3.3.8.5.1 ISS ISP H3A Poxel Extraction

From the poxel starting coordinate (the H3A_AFPAXSTART[27:16] PAXSH and H3A_AFPAXSTART[11:0] PAXSV bit fields) specifies the starting point of the poxel grid, with respect to first pixel of the input image frame.

The poxel starting coordinate also indicates which color pixels are extracted if VF is enabled (that is, if H3A_PCR[20] AF_VF_EN = 1). Normally, either Gr or Gb is used for AF, but it is not important to the hardware whether it is red, green, or blue. If VF is not enabled, then the red, green, and blue pixel extraction is controlled by the H3A_PCR[13:11] RGBPOS bit field to extract the correct colors from the input stream. Figure 9-115 shows the available options for this bit field. The red and blue pixel positions are interchangeable. For each 2 × 2 grid, the green pixels are summed to create a single value. Because of this, the amplitude of the green output contains 2 pixels, while the red and blue outputs each contain 1 pixel.

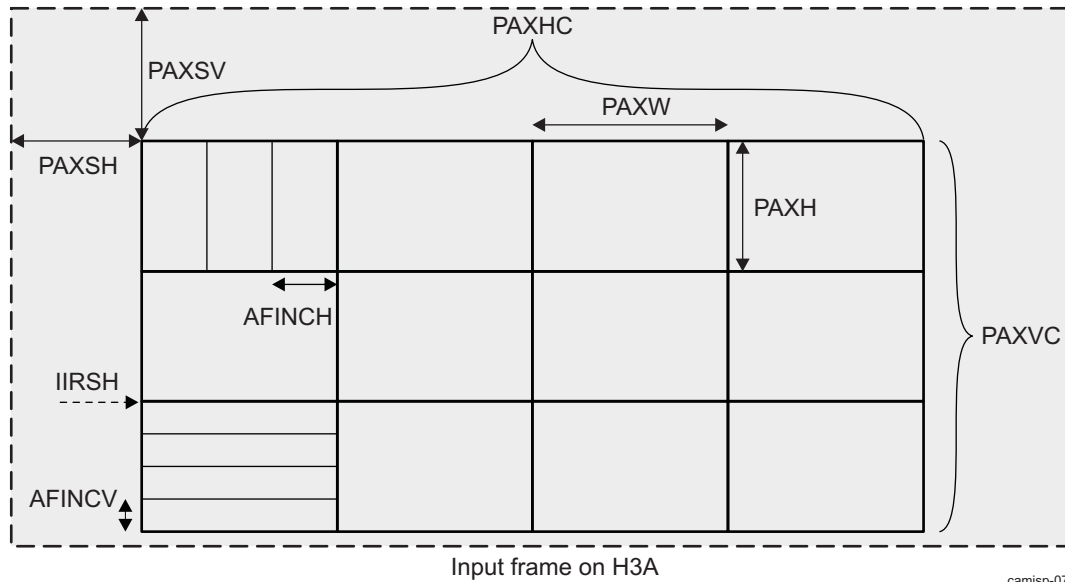

Figure 9-115. ISS ISP H3A Red, Green, and Blue Pixel Extraction Examples

camisp-068

Each paxel is $H3A_AFPAX1[23:16]$ PAXW x $H3A_AFPAX1[7:0]$ PAXH (width x height) pixels. Inside each paxel, horizontal FV can skip lines, operating on one every $H3A_AFPAX2[16:13]$ AFINCV lines. Vertical FV can skip columns, operating on one every $H3A_AFPAX2[20:17]$ AFINCH columns. Up to 32 columns are supported for each paxel. If floor (PAXW/AFINCH) \geq 32, only the first 32 designated columns are operated on. Because PAXW, PAXH, AFINCV, and AFINCH are all even numbers, AF always operates on the same green color, Gr or Gb. IIR filters for the horizontal FVs start operation at column $H3A_AFIIRSH[11:0]$ IIRSH.

Figure 9-116 shows the ISS ISP H3A horizontal/vertical fv paxel configuration.

Figure 9-116. ISS ISP H3A Horizontal/Vertical FV Poxel Configuration

NOTE: $(H3A_AFPAXSTART[27:16] PAXSH) + (H3A_AFPAX2[5:0] PAXHC) \times (H3A_AFPAX1[23:16] PAXW) \leq [(Frame\ width\ on\ VP) - (H3A_LINE_START[15:0] LINE_START)] \leq 2816$

Table 9-226 lists the bit fields that configure the size and number of paxels.

Table 9-226. ISS ISP H3A Poxel Register Field Descriptions

Bit Field	Bit Width	Description
H3A_AFPAX1[23:16] PAXW	8	Poxel width (in pixels)
H3A_AFPAX1[7:0] PAXH	8	Poxel height (in lines)
H3A_AFPAX2[5:0] PAXHC	6	Poxel count for horizontal direction
H3A_AFPAX2[12:6] PAXVC	7	Poxel count for vertical direction
H3A_AFPAX2[16:13] AFINCV	4	Line increments in a poxel
H3A_AFPAX2[20:17] AFINCH	4	Column increments in a poxel
H3A_AFPAXSTART[27:16] PAXSH	12	Poxel start position H
H3A_AFPAXSTART[11:0] PAXSV	12	Poxel start position V
H3A_AFIIRSH[11:0] IIRSH	12	IIR filter start position

The H3A AF engine also has an option for an advanced or normal stats collection mode. When 0xCA00 is written to the [H3A_ADVANCED\[31:15\]](#) ID bit field, then [H3A_ADVANCED\[0\]](#) AF_MODE can be used to toggle between normal and advanced AF stats collection mode. When the advanced AF stats collection mode is enabled, the ZEROS section of the AF poxel packet is filled with the sum of the maximum FVs, regardless of the color, from HFV_1 and HFV_2.

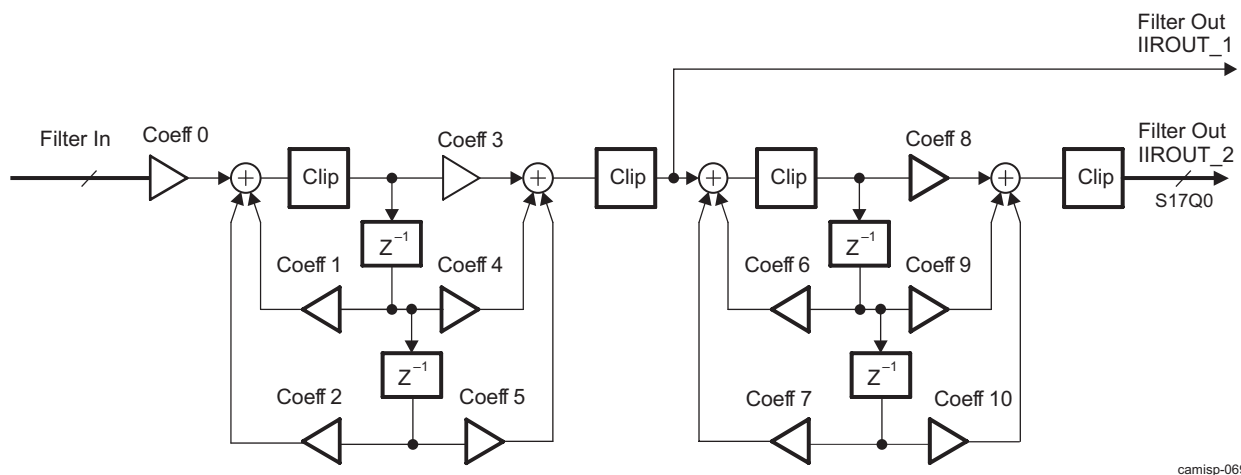

9.3.3.8.5.2 ISS ISP H3A Horizontal FV Calculator

The FV calculator takes the unsigned red/green/blue extracted data and subtracts 128 or 512 (depending on whether A-Law is enabled) to place the data in the range -128 to 127 or -512 to 511 .

After removing the offset, the data is sent through two parallel IIR filters configured in a dual-biquad configuration. Each filter uses a unique set of 11 programmable coefficients. Each coefficient is 12-bits-wide with 6 bits of decimal, S12Q6 (H3A_AF0COEF010 to H3A_AF0COEF0010 for SET0, and H3A_AF0COEF110 to H3A_AF0COEF1010 for SET1). The filter-shift registers are cleared on each horizontal line at the position set by the register IIR horizontal start register (the H3A_AFIIRSH[11:0] IIRSH bit field). The absolute values of the output (16 bits wide with 4 bits of decimal, U16Q4) of both filters are then sent to the AF accumulator module. Signed clipping is performed during the FV calculation. If the input value is m bits (signed) and the required output value is n bits, clipping transforms the input to between -2^1 and 2^1 . Values lower than -2^1 are set to -2^1 , and values higher than 2^1 are set to 2^1 .

Figure 9-117 shows the IIR filter model.

Figure 9-117. ISS ISP H3A IIR Filter Model

9.3.3.8.5.3 ISS ISP H3A HFV Accumulator

The horizontal focus value (HFV) accumulator takes the output of the horizontal IIR filter and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 9-226 lists the register fields that configure the size and number of paxels:

- In peak mode (H3A_PCR[14] FVMODE = 0x1), the maximum value is accumulated.
- In sum mode (H3A_PCR[14] FVMODE = 0x0), all HFV_n are accumulated in a paxel.

The following equations detail the calculation for:

- Sum of pixel values used in HFV: The pixel values that are used for filtering and accumulation of HFV are also accumulated in this sum of pixel values.
- HFV_n (HFV_{n_peak} for peak mode or HFV_{n_sum} for sum mode)
- HFV_count_n
- HFV_sq_n (HFV_sq_{n_peak} for peak mode or HFV_sq_{n_sum} for sum mode)

$n = 1$ or 2 for IIR1 and IIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
for (k=0; k<PAXH) // Loop on paxel rows
{
    rowpeak_n = 0;

    for (l=0; l<PAXW; l++) // Loop on values within a row
    {
        aIIRout_n = ABS(IIRout_n);
    }
}
```

```

    if (aIIRout_n >= threshold_n)
    {
        hfval = aIIRout_n - threshold_n;
        HFV_count_n++;
    }
    else hfval = 0;
    if (hfval > rowpeak_n)
    {
        rowpeak_n = HFV_n;
    }
    HFV_n_sum += hfval;
    HFV_sq_n_sum += (hfval* hfval + RNDADD) >> RNDSHIFT;
} // Finished looping on values in a row
HFV_n_peak += rowpeak_n;
HFV_sq_n_peak += (rowpeak_n * rowpeak_n + RNDADD) >> RNDSHIFT;
}

```

- threshold_n is [H3A_HVF_THR\[15:0\]](#) HTHR1 and [H3A_HVF_THR\[31:16\]](#) HTHR2, respectively.
- IIRout_n is the IIRout_1 and IIRout_2 outputs, respectively.
- HFV_count_n and HFV_sq_n are not sent to the DMA interface if VF is disabled.
- RNDADD and RNDSHIFT depend on whether input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.
- If VF is enabled, only the green color channel values are output to the DMA interface.
- In sum mode:
 - HFV_n = HFV_n_sum
 - HFV_sq_n = HFV_sq_n_sum
- In peak mode:
 - HFV_n = HFV_n_peak
 - HFV_sq_n = HFV_sq_n_peak

9.3.3.8.5.4 ISS ISP H3A VFV Calculator

The VFV calculator takes the unsigned extracted data through two FIR filters, each with a set of five coefficients (VCOEF1_x, where x = 0 to 4, in the [H3A_VFV_CFG1](#) and [H3A_VFV_CFG2](#) registers for FIR 1, and VCOEF2_x, where x = 0 to 4, in the [H3A_VFV_CFG3](#) and [H3A_VFV_CFG4](#) registers). Each coefficient is 8 bits wide with 4 bits of decimal (S8Q4). The filter outcome is downshifted by 4 bits and takes an absolute value to produce a 16-bit unsigned value. This is then sent to threshold [H3A_VFV_CFG2\[31:16\]](#) VTHR1 for FIR 1, and [H3A_VFV_CFG4\[31:16\]](#) VTHR2 for FIR 2, and square logic to produce VFV_n and VFV_sq_n.

9.3.3.8.5.5 ISS ISP H3A VFV Accumulator

The VFV accumulator takes the output of the vertical FIR filters and accumulates values for each pixel. The size and number of pixels is configurable by registers.

[Table 9-226](#) lists the bitfields that configure the size and number of pixels.

The following equations detail the calculation for:

- VFV_n
- VFV_count_n
- VFV_sq_n

n = 1 or 2 for FIR1 and FIR2, respectively.

For each pixel, these six values are available for each R, G, and B component.

```

FIR_coef_n = [VCOEFn_0, VCOEFn_1, VCOEFn_2, VCOEFn_3, VCOEFn_4]; /* coefficient values in S8.4
format */
aFIRout_n = (ABS(inner_product(extracted_G, FIR_coef_n)) + 8) >> 4;

```

```

if (aFIRout_n >= threshold_n)
{
  VFV_n = aFIRout_n - threshold_n;
  VFV_count_n++;
}
else VFV_n = 0;

VFV_sq_n = (VFV_n * VFV_n + RNDADD) >> RNDSHIFT;

```

- threshold_n is H3A_VFV_CFG2[31:16] VTHR1 and H3A_VFV_CFG4[31:16] VTHR2, respectively.
- FIRout_n is the FIRout_1 and FIRout_2 outputs, respectively.
- RNDADD and RNDSHIFT depend on whether the input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

9.3.3.8.6 ISS ISP H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows, and then subsamples each window into 2 × 2 blocks. For each subsampled 2 × 2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2 × 2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

The AE/AWB module has three output format modes, which are set through the H3A_AEWCFG[9:8] AEFMT bit field:

- Sum of square mode: H3A_AEWCFG[9:8] AEFMT = 0x0
- Min/max mode: H3A_AEWCFG[9:8] AEFMT = 0x1
- Sum-only mode: H3A_AEWCFG[9:8] AEFMT = 0x2

9.3.3.8.6.1 ISS ISP H3A Subsembler

The subsampler partitions the frame into windows using the size, count, and starting location parameters shown on the left in Figure 9-118. Each window is further sampled down to a set of 2 × 2 blocks. The horizontal and vertical distances between the start of blocks within a window is programmable using the parameters shown on the right in Figure 9-118.

Figure 9-118. ISS ISP H3A AE/AWB Window Configurations

camisp-072

Table 9-227 lists the bit fields that configure the window and block sizes, counts, and starting positions.

Table 9-227. ISS ISP H3A AE/AWB Window Register Field Descriptions

Bit Field	Bit Width	Description
H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
H3A_AEWINSTART[11:0] WINSH	12	Window start position H
H3A_AEWINSTART[27:16] WINSV	12	Window start position V
H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples

9.3.3.8.6.2 ISS ISP H3A Additional Black Row of AE/AWB Windows

In addition to the 128 rows of windows, the AE/AWB module provides support for an additional row of windows for black data. This data may be useful in determining the DC offset noise of the rest of the data. The black row of windows can be before or after the regular rows of windows. The vertical start line for the black row of windows is specified in the H3A_AEWINBLK[27:16] WINSV bit field, and the height is specified in the H3A_AEWINBLK[6:0] WINH bit field. The horizontal starting pixel and horizontal width of the black row of windows are the same as for the regular rows of windows.

Figure 9-119 shows a black row of windows before rows of windows.

Figure 9-119. ISS ISP H3A Black Row of Windows Before Regular Rows of Windows

camisp-075

Table 9-228 lists the bit fields that configure the window and block sizes, counts, and starting positions.

Table 9-228. ISS ISP H3A AE/AWB Window With Additional Black Row Register Field Descriptions

Bit Field	Bit Width	Description
H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
H3A_AEWINSTART[11:0] WINSH	12	Window start position H

Table 9-228. ISS ISP H3A AE/AWB Window With Additional Black Row Register Field Descriptions (continued)

Bit Field	Bit Width	Description
H3A_AEWINSTART [27:16] WINSV	12	Window start position V
H3A_AEWSUBWIN [3:0] AEWINCH	4	Horizontal distance between subsamples
H3A_AEWSUBWIN [11:8] AEWINCV	4	Vertical distance between subsamples
H3A_AEWINBLK [27:16] WINSV	12	Window start position H for single black line
H3A_AEWINBLK [6:0] WINH	7	Window height (in lines) for single black line

9.3.3.8.6.3 ISS ISP H3A Saturation Check

The saturation check module compares the data from the subsampler to the value programmed in the [H3A_PCR](#)[31:22] AVE2LMT bit field. This value is the maximum clipping value. If all 4 pixels in the 2 × 2 block are less than the AVE2LMT value, the value of the unsaturated block counter is incremented. There is one unsaturated block counter per window. The unsaturated block counters are later written to memory.

9.3.3.8.6.4 ISS ISP H3A AE/AWB Accumulators

The output from the saturation check module and the subsampler module are separately accumulated for each pixel in every 2 × 2 pixel block for each window. Therefore, there are eight accumulators per window (one accumulator for each pixel in a 2 × 2 pixel block, times two sets of accumulators: clipped/saturated data and presaturated data). Each of the 4 pixels in the 2 × 2 pixel grid is associated with a color (R, Gr, B, Gb); however, the output of these accumulators is referenced by position in the grid, not color.

The accumulators are 16 bits wide, and the accumulated data is 10 bits wide. Therefore, when a window contains more than 64 pixels of the same color, an overflow risk exists. This risk can be reduced by enabling the A-Law conversion in the preprocessing stage. See [Section 9.3.3.8.4](#) for details.

The AE/AWB module has a shift value for the accumulation of pixel values that is set in the [H3A_AEWCFG](#)[3:0] SUMSHFT bit field.

9.3.3.8.7 ISS ISP H3A DMA Interface

The DMA interface module takes the data from the AF engine and AE/AWB engine and builds packets to be sent to the memory through the BL module.

The data interface has separate start pointers for the AF and AE/AWB engines.

- The starting address for the AF engine is the [H3A_AFBUFST](#)[31:5] AFBUFST bit field.
- The starting address for the AE/AWB engine is the [H3A_AEWBUFST](#)[31:5] AEWBUFST bit field.

The DMA interface module continuously loops through this data as it builds the packets. To optimize the transfer sizes, the DMA interface sends out an AF or AE transfer for each row of pixels or windows. This requires that each horizontal row of pixels or windows starts and ends on a 32-byte boundary. If a horizontal row of pixels or windows ends on a non-32 byte boundary, the hardware packs zeroes. The counts for the AEW that occur every eight windows is sent in the row with the eighth consecutive window.

[Table 9-229](#) lists the packet formats for AF with vertical AF disabled.

Table 9-229. ISS ISP H3A AF Packet Format With Vertical AF Disabled

9.3.3.8.8 ISS ISP H3A Events and Status Checking

The AF and AEW engines generate an interrupt event at the end of processing each frame. However, these two interrupts are internally tied together so that only one H3A interrupt signal is generated. If the AF engine and AEW engine do not process the same frame concurrently, this should not be an issue. However, if they do run concurrently, one of two outcomes may occur:

- The H3A interrupt may seem to trigger only once for each frame. This can happen when the processing for the AF and AEW engines finishes at or near the same time. The interrupt service routine (ISR) does not have enough time to clear the interrupt flag for the first interrupt before the second interrupt occurs.
- The H3A interrupt may trigger twice for each frame. This can happen when the AF engine or the AEW engine finishes processing the frame much earlier than the other engine. In this case, the ISR does have enough time to clear the interrupt flag for the first interrupt by the time the second interrupt occurs.

The outcome depends on the difference in location of the last pixel/window in the frame (determines when processing is finished), the frequency of the relative clocks in the system, the occurrence and triggering of other interrupts in the system, and the latencies of the context switching and ISR execution.

The [H3A_PCR\[15\] BUSYAF](#) and/or [H3A_PCR\[18\] BUSYAEAWB](#) status bits are set when the start of frame occurs (if the [H3A_PCR\[0\] AF_EN](#) and/or [H3A_PCR\[16\] AEW_EN](#) bits are 1 at that time). They are automatically reset to 0 at the end of processing a frame. The [H3A_PCR\[15\] BUSYAF](#) and/or [H3A_PCR\[18\] BUSYAEAWB](#) status bits may be polled to determine the end of frame status.

9.3.3.9 ISS ISP ISIF Functional Description

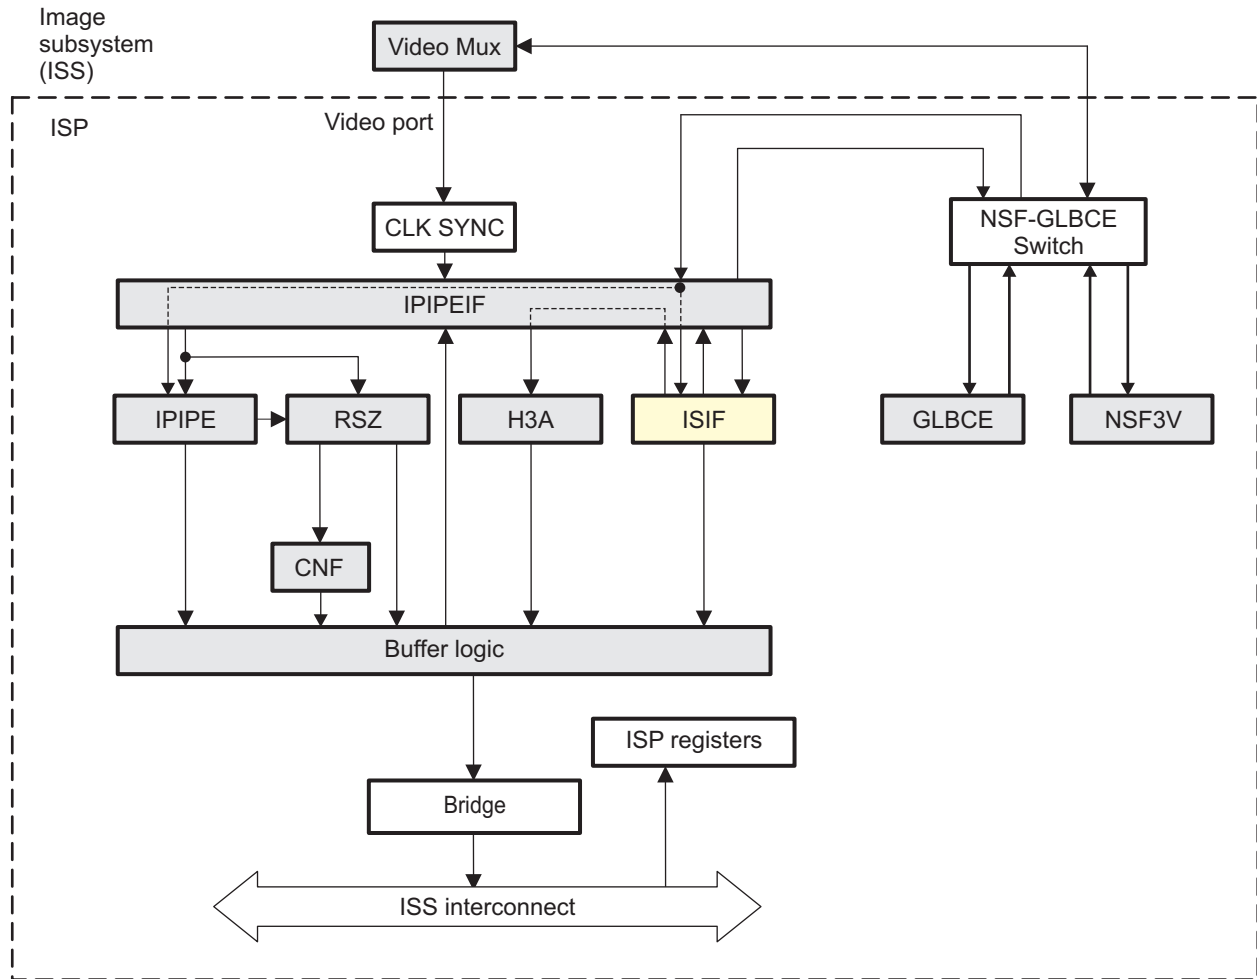

9.3.3.9.1 ISS ISP ISIF Overview

The ISIF module receives RAW or YUV4:2:2 data from the IPIPEIF module. The module outputs data back to the IPIPEIF module and can also output data to memory through the BL module. The ISIF module can process the incoming data and supports the following functions:

- Maximum supported image size is 32,768 × 32,768
- Supports up to 16-bit analog front end
- Sensor data linearization
- Supports Bayer and Foveon® input data format (RGB and CMYG color support)
- Supports VGA read out mode
- Supports various image data format
- Color space conversion
- Digital clamp with horizontal/vertical offset drift compensation
- Vertical line defect correction
- Programmable 2D-matrix LSC
- Gain and offset control
- Programmable horizontal/vertical culling pattern
- Maximum pixel rate clock of 532 MPix/s on the VP interface.
- 10-to-8-bit A-Law compression table inside
- 12-bit pack supported when written to memory

[Figure 9-121](#) show the ISIF module connections to other submodules of the ISP.

Figure 9-121. ISS ISP ISIF High-Level Diagram

camisp-003a

9.3.3.9.2 ISS ISP ISIF Top-Level Block Diagram

Figure 9-122 shows the different blocks of the ISIF module.

Figure 9-122. ISS ISP ISIF Top-Level Block Diagram

camisp-074

The following sections describe the blocks in the ISIF module.

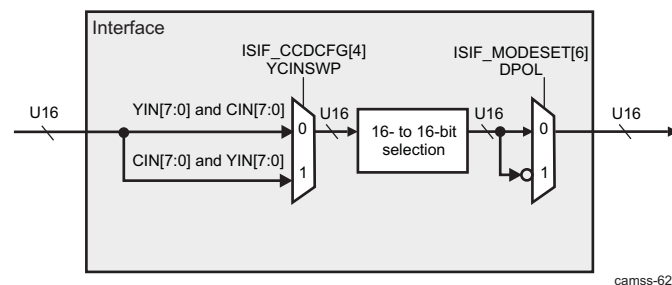

9.3.3.9.3 ISS ISP ISIF Input Interface

The input interface is a video interface. It comprises the horizontal (HD) and vertical (VD) synchronization signal, pixel clock (PCLK), and data (DATA). Table 9-234 gives more information about these different signals. The ISIF uses the HD and VD signals provided by the sensor through the VP and IPIPEIF. The pixel clock clocks data into the ISIF at a maximum rate of 532 MHz.

Table 9-234. ISS ISP ISIF Input Interface Signals

Name	I/O	Function
VD	I	Vertical sync signal
HD	I	Horizontal sync signal
PCLK	I	Pixel clock. This signal is the pixel clock used to load image data into the ISIF. The clock controller can configure to trigger on the rising or falling edge of the PCLK signal.
DATA	I	Data. The data interface is a 16-bit interface. When the ISIF is configured to write data to SDRAM, the write-enable signal allows an external device to control which data is to be written to SDRAM. The data input can be configured from the ISIF_MODESET.INPMOD register where it can be set to RAW, YCbCr (16 bits and 8 bits). The polarity of the data can be changed from the ISIF_MODESET.DPOL as shown in Figure 9-123 .

9.3.3.9.4 ISS ISP ISIF Interface

Figure 9-123. ISS ISP ISIF Interface Block Diagram

The ISIF supports 8- to 16-bit-wide RAW data signals and 8-/16-bit YCbCr signals, as described in [Table 9-235](#). The interface can be set in the three different modes from the [ISIF_MODESET\[13:12\]](#) INPMOD bit field. The [ISIF_CCDCFG\[11\]](#) Y8POS bit selects the y signal positioning whenever YUV4:2:2 is input. Moreover, if CCIR656 input is used the width of selected bit can be set through the [ISIF_CCDCFG\[5\]](#) BT656 bit.

Table 9-235. ISS ISP ISIF Data Input Formats

ISIF Input Port Name	RAW Data	16-bit YCbCr	8-bit YCbCr
Y17	C_DATA15	Y7	
Y16	C_DATA14	Y6	
Y15	C_DATA13	Y5

Y13	C_DATA11	Y3	
Y12	C_DATA10	Y2	
Y11	C_DATA9	Y1	
Y10	C_DATA8	Y0	
Cl7	C_DATA7	Cb7,Cr7	Y7,Cb7,Cr7
Cl6	C_DATA6	Cb6,Cr6	Y6,Cb6,Cr6
Cl5	C_DATA5	Cb5,Cr5	Y5,Cb5,Cr5
Cl4	C_DATA4	Cb4,Cr4	Y4,Cb4,Cr4
Cl3	C_DATA3	Cb3,Cr3	Y3,Cb3,Cr3

Table 9-235. ISS ISP ISIF Data Input Formats (continued)

ISIF Input Port Name	RAW Data	16-bit YCbCr	8-bit YCbCr
CI2	C_DATA2	Cb2,Cr2	Y2,Cb2,Cr2
CI1	C_DATA1	Cb1,Cr1	Y1,Cb1,Cr1
CI0	C_DATA0	Cb0,Cr0	Y0,Cb0,Cr0

Y and C input signals can be swapped through the [ISIF_CCDCFG\[4\]](#) YCINSWP bit.

In case of RAW data at ISIF input, a 16- to-16-bit selection can be done: when the number of RAW data lines is less than 16, data can be connected to the upper or lower lines of C_DATA[15:0]. Lines not connected must be tied low. As shown in [Table 9-236](#), the [ISIF_CGAMMAWD\[4:1\]](#) GWDI bit field must be configured correctly so that the MSB of the input is connected to the MSB of the 16-bit data bus in ISIF.

Table 9-236. ISS ISP ISIF Raw Data Connection: Selects MSB Position of Input Data

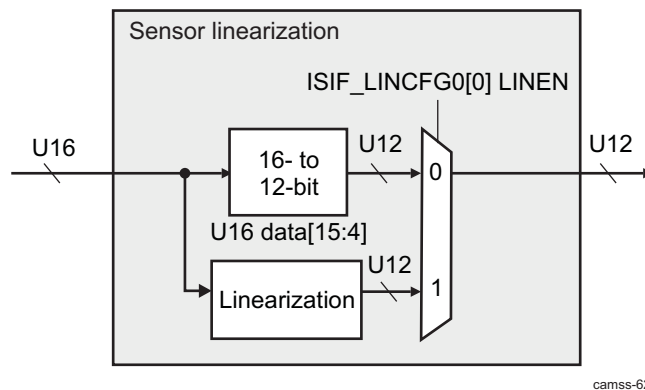

ISIF_CGAMMAWD[4:1] GWDI	16-to-16-bit Selection
0	C_DATA[15:0] = C_DATA[15:0]
1	C_DATA[15:0] = C_DATA[14:0] &0
2	C_DATA[15:0] = C_DATA[13:0] &00
3	C_DATA[15:0] = C_DATA[12:0] &000
4	C_DATA[15:0] = C_DATA[11:0] &0000
5	C_DATA[15:0] = C_DATA[10:0] &00000
6	C_DATA[15:0] = C_DATA[9:0] &000000
7	C_DATA[15:0] = C_DATA[8:0] &0000000
8	C_DATA[15:0] = C_DATA[7:0] &00000000

The polarity of the input image data can be switched through the [ISIF_MODESET\[6\]](#) DPOL bit.

9.3.3.9.5 ISS ISP ISIF Sensor Linearization

NOTE: For the memory access locations of the sensor linearization table, see [Section 9.3.3.11](#), *ISS ISP Memory Mapping*.

Figure 9-124. ISS ISP ISIF Sensor Linearization Block Diagram

The sensor linearization module can correct for the nonlinear response of image sensors. A LUT is programmed with an offset value to add to the original pixel value based on the original pixel value.

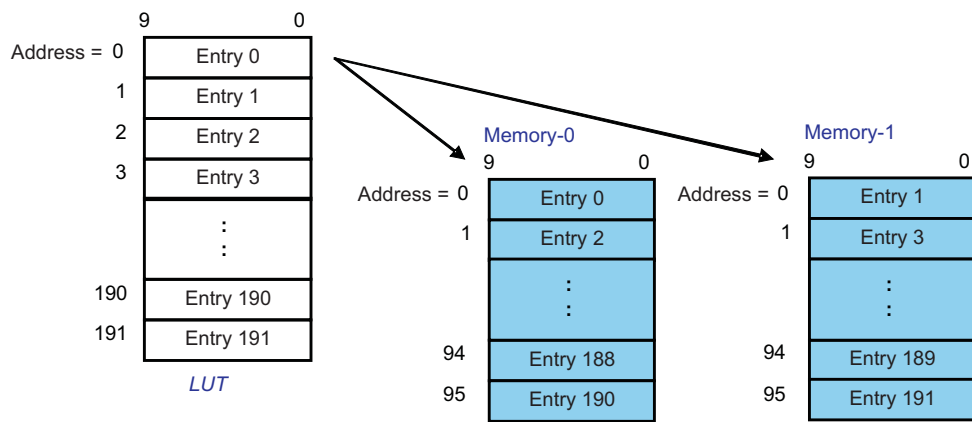

The LUT is a sampling of the linearization correction curve based on calibration of the image sensor. Intermediate values between sampling points are computed using linear interpolation. The entire correction curve is divided into seven regions, as listed in [Table 9-237](#). The regions for the darkest part and the brightest part of the response curve have dense sampling. The linearization mode can be a uniform or a nonuniform sampling and can be set through the [ISIF_LINCFG0\[1\]](#) LINMD bit.

Table 9-237. ISS ISP ISIF Linearization LUT

Region	Number of Sample Points	LUT Address
table_in[15:11] == 00000	32	table_in[10:6]
table_in[15:11] == 00001	4	table_in[10:9] + 32
table_in[15:12] == 0001	4	table_in[11:10] + 36
table_in[15:13] == 001	4	table_in[12:11] + 40
table_in[15:14] == 01	4	table_in[13:12] + 44
table_in[15:14] == 10	16	table_in[13:10] + 48
table_in[15:14] == 01	128	table_in[13:7] + 64

The LUT has 192 entries and is split into two 96 × 10-bit memories, as shown in Figure 9-125. Table 9-238 is mapped in the memory map. The LUT entries are interleaved between memory 0 and memory 1.

Figure 9-125. ISS ISP ISIF Linearization LUT Memories

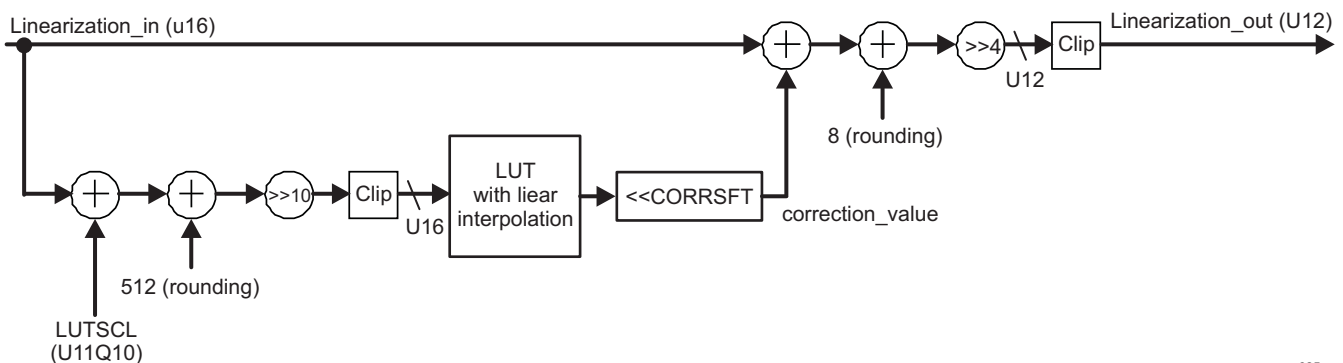

camss-613

Table 9-238. ISS ISP ISIF LUT Memory Region

Memory Region	Address Range	Description
Memory 0	0xC000 – 0xC17F	ISIF linearity compensation LUT 0
Memory 1	0xC400 – C57F	ISIF linearity compensation LUT 1

A scale factor is applied to the input before lookup through the ISIF_LINCFG1[10:0] LUTSCL bit field. The LUT entries are signed 10-bit data (u16). After linear interpolation, the correction value is left-shifted by a programmable amount (the ISIF_LINCFG0[6:4] CORRSFT bit field), and then added to the input. This is then converted to unsigned 12-bit by right shift, followed by clipping.

Figure 9-126. ISS ISP ISIF Linearization Block Diagram

camss-625

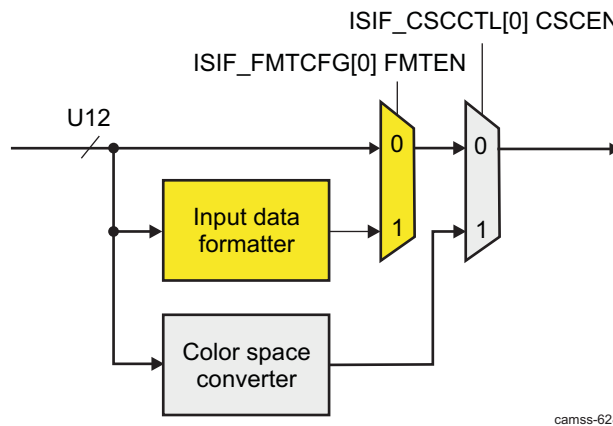

To enable the linearization module, set the [ISIF_LINCFG0\[0\] LINEN](#) bit to 1.

If the linearization module is disabled ([ISIF_LINCFG0\[0\] LINEN](#) = 0x0), a 16- to-12-bit transformation is done, and the upper 12 bits of U16 input are sent to the next block.

9.3.3.9.6 ISS ISP ISIF Input Data Formatter

Figure 9-127 shows the ISS ISP ISIF input data formatter block diagram.

Figure 9-127. ISS ISP ISIF Input Data Formatter Block Diagram

There are two functional blocks: input data formatter and color space converter, which use two 2816 × 12-bit memories (corresponds to one line of maximum 2816 pixels with each pixel equal to 12 bits). Only one of the function blocks can be enabled.

The input data formatter block allows the ISIF to handle a wide variety of current and future readout schemes other than Bayer format. Two line memories and a programmable address generator are used to translate those patterns into a standard Bayer pattern (or any other pattern). This allows the back-end processing (noise filters, interpolation, histogram, 3A statistics) to remain unchanged.

The input data formatter block also supports divided input lines. In case an input line is divided into multiple lines and fed to the ISIF, the formatter gathers the divided lines and organizes a single line. Up to four divided lines can be supported.

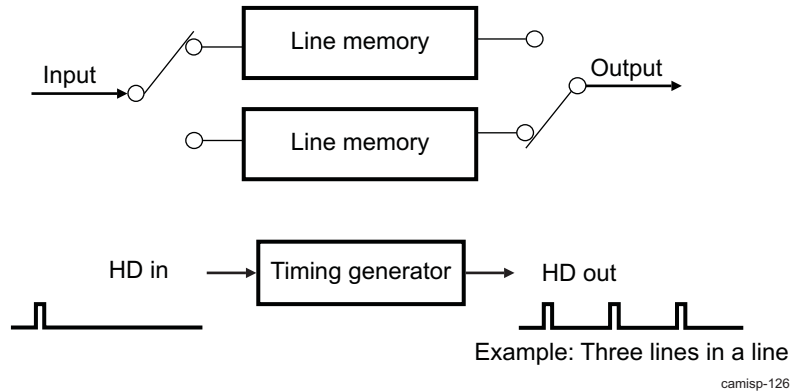

The input data formatter is enabled through the [ISIF_FMTCFG\[0\] FMTEN](#) bit.

The input data formatter can split an input line into one, two, three, or four output lines, or can combine the divided by one, two, three, or four input lines into a single line.

- Set the [ISIF_FMTCFG\[1\] FMTCBL](#) bit to 0 for split mode.
- Set the [ISIF_FMTCFG\[1\] FMTCBL](#) bit to 1 for combine mode.
- Select the number of lines in the [ISIF_FMTCFG\[5:4\] LNUM](#) bit field.

The input data formatter can work in normal or line alternative mode. The choice is done through the [ISIF_FMTCFG\[2\] LNALT](#) bit.

Figure 9-128 shows an example of generating three output lines from an input line with a new, internally generated HD signal.

Figure 9-128. ISS ISP ISIF Splits an Input Line Into Three Output Lines

This HD signal then gates the downstream processing rather than the original sensor HD signal. Descriptions of how to configure the formatter are provided in the following sections.

Because the size of the line memories is 2816×12 bits, the following restrictions apply for the data formatter:

- Split mode:
 - The maximum number of pixels that can be supported in an output line if the input line is transformed into one output line is 2816.
 - The maximum number of pixels that can be supported in an output line if the input line is transformed into two output lines is 1408.
 - The maximum number of pixels that can be supported in an output line if the input line is transformed into three output lines is 938.
 - The maximum number of pixels that can be supported in an output line if the input line is transformed into four output lines is 704.
- Combine mode:
 - The maximum number of pixels that can be supported in an input line if one input line is transformed into an output line is 2816.
 - The maximum number of pixels that can be supported in an input line if two input lines are transformed into an output line is 1408.
 - The maximum number of pixels that can be supported in an input line if three input lines are transformed into an output line is 938.
 - The maximum number of pixels that can be supported in an input line if four input lines are transformed into an output line is 704.

9.3.3.9.6.1 ISS ISP ISIF Formatter Area Settings

As shown in [Figure 9-129](#), the following registers are used to set the formatter area:

- [ISIF_FMTSPH](#)
- [ISIF_FMTLNH](#)
- [ISIF_FMTLSV](#)
- [ISIF_FMTLNV](#)

Figure 9-129. ISS ISP ISIF Input Data Formatter Area Settings

camisp-112

Table 9-239 and Table 9-240 describe these registers. The input line is input to the formatter, and the output line is output from the formatter.

Table 9-239. ISS ISP ISIF Input Data Formatter Area Setting Registers

Register	Description
ISIF_FMTSPH	The first valid pixel of an input line
ISIF_FMTLNH	Valid length of a input line = FMTLNH + 1
ISIF_FMTLSV	The first valid input line
ISIF_FMTLNV	The number of the valid input lines = FMTLNV + 1

Table 9-240. ISS ISP ISIF Output Data Formatter Area Setting Registers

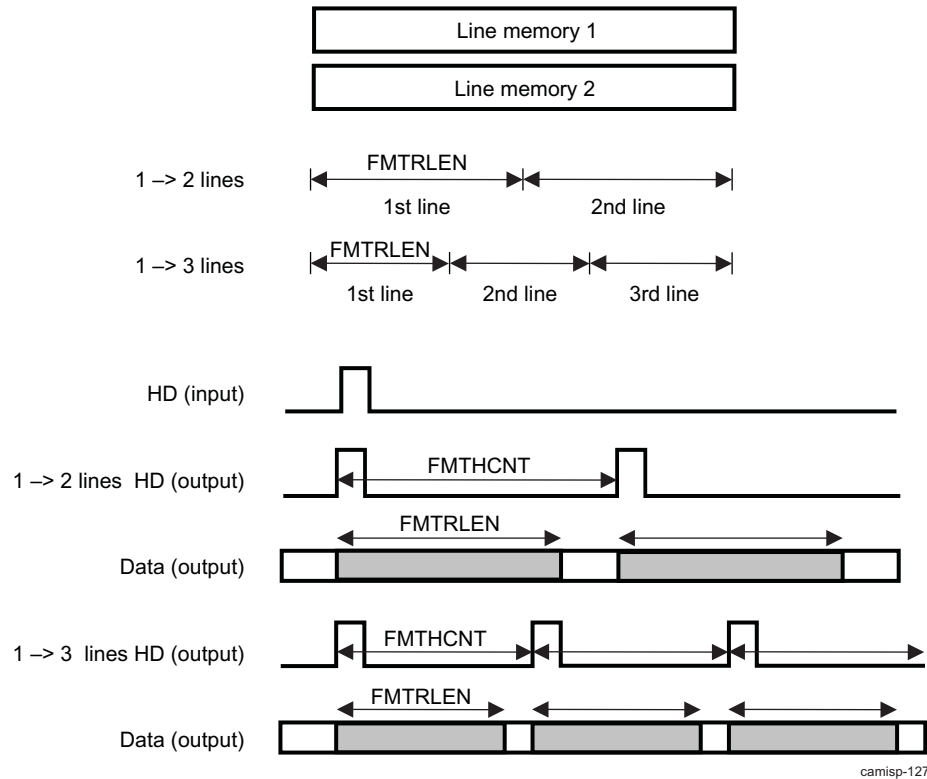

Register	Description
ISIF_FMTRLEN	The length of an output line
ISIF_FMTHCNT	HD interval for output lines
ISIF_SPH	The first pixel in an output line to be stored to SDRAM
ISIF_LNH	The number of pixels in an output line to be stored to SDRAM = LN + 1 (Actual number of output pixels is a multiple of 16)
ISIF_LNV	The number of the output lines to be stored to SDRAM = LNV + 1
ISIF_CBN	The number of the output lines stored in the circular buffer. If CBN=0, circular buffer is not used and the memory space is used as a flat space

The number of pixels in an output line to be stored to SDRAM is a multiple of 16. If the number of pixels is not aligned, the last few pixels are not written to SDRAM. For example, if CULH=0xFFFF, actual output pixels to SDRAM is equal to 16 x floor((LNH+1)/16). If CULH is not 0xFFFF, output pixels to SDRAM is equal to 16 x floor(w/16), where w is the number of pixels after horizontal culling specified by CULH.

The number of pixels in an output line must be set to the ISIF_FMTRLEN register, and the HD output interval must be set to the ISIF_FMTHCNT register. It is not necessary to set the ISIF_FMTHCNT register if multiple input lines are combined into a single line.

Figure 9-130 shows an example of splitting an input line into two or three output lines.

Figure 9-130. ISS ISP ISIF Data Formatter Output Control Example

9.3.3.9.6.2 ISS ISP ISIF Formatter Programming

The data formatter derives its flexibility by supporting up to 16 different addresses and a program that can contain up to 32 entries.

Address pointer

There are 16 address pointer registers ([ISIF_FMTAPTR0](#) to [ISIF_FMTAPTR15](#)), which contain:

- The [ISIF_FMTAPTRx\[14:13\]](#) LINE bit field: 2-bit line number to specify the output line to which it belongs: 0, 1, 2, or 3. It is valid only for the line splitting.
- The [ISIF_FMTAPTRx\[12:0\]](#) INIT bit field: 13-bit initial address for pointer x (where x = 0 to 15)

Each address value is auto-incremented or auto-decremented by a programmable value (the [ISIF_FMTCFG\[11:8\]](#) FMTAINC bit field).

Program

There are 32 program entry registers, which contain:

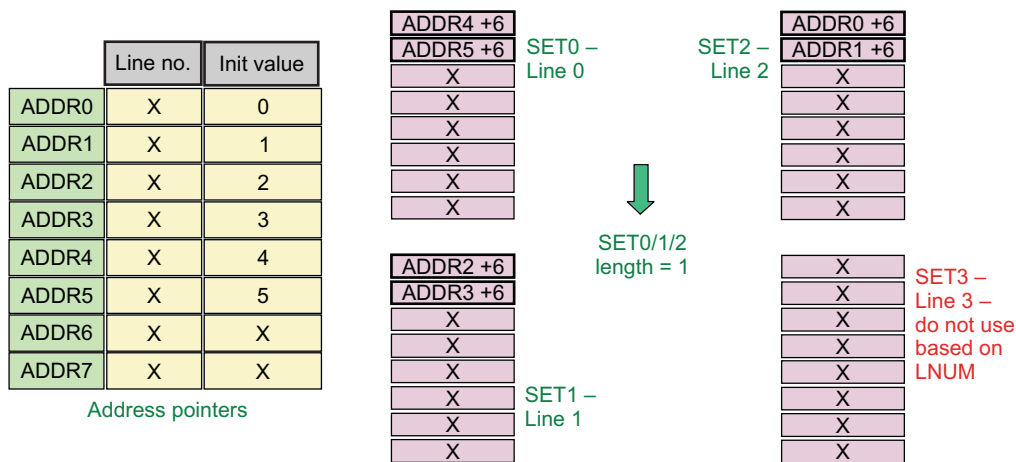

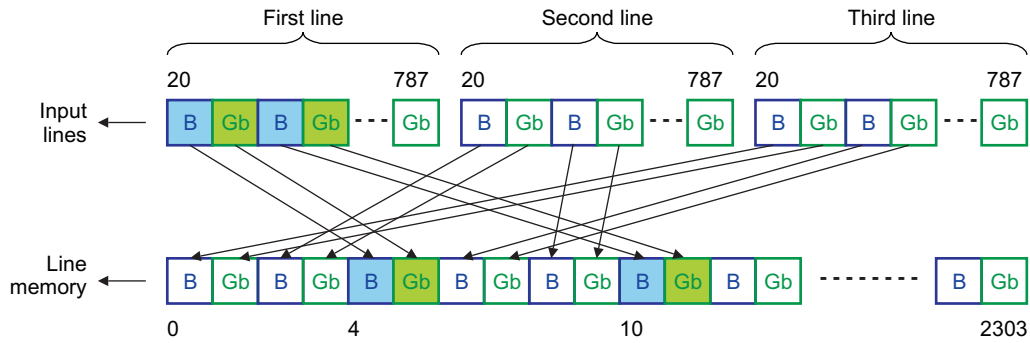

- In the [ISIF_FMTPGMVFO](#) and [ISIF_FMTPGMVF1](#) registers: The PGMxxEN fields set the program entry valid flag (where xx = 00 to 31) .
- In the [ISIF_FMTPGMAPS0](#) to [ISIF_FMTPGMAPS7](#) registers: The PGMxxAPTR fields specify the program xx address pointer (where xx = 00 to 31).
- In the [ISIF_FMTPGMAPU0](#) and [ISIF_FMTPGMAPU1](#) registers: The PGMxxUPDT fields set the program xx address update (increment or decrement) (where xx = 00 to 31).

Because each program entry has a valid flag, the formatter can also support images larger than the memory limit (length: 4480) by not choosing some of the entries.

The total program memory of 32 entries is divided into two or four sets:

- Program memory of 16 entries each for odd and even lines to split the line:

Figure 9-134. ISS ISP ISIF Example of Combining Three Input Lines Into a Single Line

camisp-131

Table 9-241 lists an example of the ISS ISP ISIF combining three input lines into a single line.

Table 9-241. ISS ISP ISIF Example of Combining Three Input Lines Into a Single Line: Register Setting Example

Step	Configuration Required	Size

9.3.3.9.7 ISS ISP ISIF Color Space Converter

Figure 9-135 shows the ISS ISP ISIF Color Space Converter Block Diagram.

Figure 9-135. ISS ISP ISIF Color Space Converter Block Diagram

The color space converter (CSC) includes four 8-bit × 12-bit multipliers and one adder for the color space conversion. These multiplier/adder units are used for the operation described in Figure 9-136. Data are taken from two input lines during the operation.

Coefficients are signed 8-bit (decimal is 5 bits). Coefficients are set through the following registers:

- Coefficient M00: [ISIF_CSCM0\[7:0\]](#) CSCM00
- Coefficient M01: [ISIF_CSCM0\[15:8\]](#) CSCM01
- Coefficient M02: [ISIF_CSCM1\[7:0\]](#) CSCM02
- Coefficient M03: [ISIF_CSCM1\[15:8\]](#) CSCM03
- Coefficient M10: [ISIF_CSCM2\[7:0\]](#) CSCM10
- Coefficient M11: [ISIF_CSCM2\[15:8\]](#) CSCM11
- Coefficient M12: [ISIF_CSCM3\[7:0\]](#) CSCM12
- Coefficient M13: [ISIF_CSCM3\[15:8\]](#) CSCM13
- Coefficient M20: [ISIF_CSCM4\[7:0\]](#) CSCM20
- Coefficient M21: [ISIF_CSCM4\[15:8\]](#) CSCM21
- Coefficient M22: [ISIF_CSCM5\[7:0\]](#) CSCM22
- Coefficient M23: [ISIF_CSCM5\[15:8\]](#) CSCM23
- Coefficient M30: [ISIF_CSCM6\[7:0\]](#) CSCM30
- Coefficient M31: [ISIF_CSCM6\[15:8\]](#) CSCM31
- Coefficient M32: [ISIF_CSCM7\[7:0\]](#) CSCM32
- Coefficient M33: [ISIF_CSCM7\[15:8\]](#) CSCM33

camss-618

The CSC can convert CMYG filtered CCD data to Bayer matrix (RGBG) data, as shown in Figure 9-137.

Figure 9-137. ISS ISP ISIF Color Space Converter Operation: CMYG to RGBG

camisp-113

Figure 9-138 through Figure 9-140 show which input pixels are used for the operation. There is 1line latency between the input and the output.

Figure 9-138. ISS ISP ISIF Color Space Conversion Example

camisp-114

Figure 9-139. ISS ISP ISIF First Pixel/First Line Generation

camisp-115

Figure 9-140. ISS ISP ISIF Second Pixel/First Line Generation

camisp-116

As shown in [Figure 9-141](#) through [Figure 9-144](#), the operation for the last pixel and the second last pixel uses the same input data.

Figure 9-141. ISS ISP ISIF Second Last Pixel/First Line Generation

camisp-117

Figure 9-142. ISS ISP ISIF Last Pixel/First Line Generation

camss-118

Figure 9-143. ISS ISP ISIF First Pixel/Last Line Generation

camisp-119

Figure 9-144. ISS ISP ISIF Second Pixel/Last Line Generation

camisp-120

Also, the operation for the last line and the second last line uses the same input data (see [Figure 9-145](#) and [Figure 9-146](#)).

Figure 9-145. ISS ISP ISIF Second Last Pixel/Last Line Generation

camisp-121

Figure 9-146. ISS ISP ISIF Last Pixel/Last Line Generation

camisp-122

In addition to the registers specific to the CSC, some of the registers are shared with the input data formatter to configure the valid area:

- [ISIF_FMTSPH](#)
- [ISIF_FMTLNH](#)
- [ISIF_FMTLSV](#)
- [ISIF_FMTLNV](#)

There must be at least 1 invalid pixel at the end of the line and one invalid line at the end of the frame.

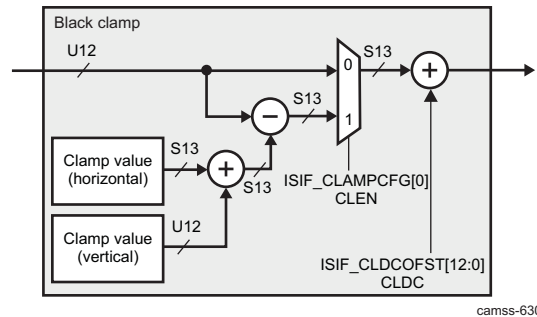

To enable the color space conversion, set the `ISIF_CSCCTL[0]` CSCEN bit to 1.

9.3.3.9.8 ISS ISP ISIF Black Clamp

NOTE: For the memory access locations of the ISIF clamp, see [Section 9.3.3.11, ISS ISP Memory Mapping](#).

Figure 9-147 shows the ISS ISP ISIF black clamp block diagram.

Figure 9-147. ISS ISP ISIF Black Clamp Block Diagram

The clamp value is calculated based on the pixel value of the OB region of the sensor. The clamp value is calculated separately for horizontal and vertical directions to compensate the offset drift in the horizontal and vertical directions. The sum of the horizontal and vertical clamp values is subtracted from the image data, and then the additional DC offset is added (the `ISIF_CLDCOFST[12:0]` CLDC bit field, an S13Q0 value). This value is added whether the black clamp module is enabled or not.

The horizontal clamp is disabled through the `ISIF_CLAMPCFG[2:1]` CLHMD bit field.

To enable the black clamp module, set the `ISIF_CLAMPCFG[0]` CLEN bit to 1. The `ISIF_PPLN[15:0]` PPLN bit field sets the pixel per line, and the number of pixel clock periods in one line HD period equals `PPLN + 1` pixel clock. The `ISIF_PPLN[15:0]` bit field is not used when the input is already HD/VD.

9.3.3.9.8.1 ISS ISP ISIF Clamp Value for Horizontal Direction

The clamp value for horizontal direction is calculated using the pixel values at the upper OB region.

The maximum pixel value to be used for the clamp value calculation can be limited to 1023 if the pixel value limitation is enabled (`ISIF_CLHWIN0[6]` CLHLMT = 1).

Clamp value calculation for horizontal direction can be disabled if there is no upper OB region. The operating modes are:

- The horizontal clamp value calculation is enabled. The calculated horizontal clamp value is subtracted from the image data along with the vertical clamp value (`ISIF_CLAMPCFG[2:1]` CLHMD = 0x1).
- The horizontal clamp value is not updated. The horizontal clamp value used for the previous image is subtracted from the image data along with the vertical clamp value (`ISIF_CLAMPCFG[2:1]` CLHMD = 0x2).
- The horizontal clamp value is not updated. Only the vertical clamp value is subtracted from the image data (`ISIF_CLAMPCFG[2:1]` CLHMD = 0x0).

The number of windows in a row is set with the `ISIF_CLHWIN0[4:0]` CLHWC bit field.

Up to 32 windows in a row can be set for clamp value calculation. All the windows have the same size in a format $2^{(ISIF_CLHWIN0[9:8] \text{ CLHWM}+5)}$ pixels by $2^{(ISIF_CLHWIN0[13:12] \text{ CLHWN}+1)}$ lines.

The `ISIF_CLHWIN2[12:0]` CLHSV and `ISIF_CLHWIN1[12:0]` CLHSH bit fields enable setting the position of the first optical black clamp window in the frame. The pixel and line offset are in a range 0 to 8191. The `ISIF_HDW` register sets the width of the HD.

Figure 9-148 shows the ISS ISP ISIF clamp value for the horizontal direction.

- Case 2: $\text{interpolated_clamp_win}_x = (\text{clamp_win}_i - \text{clamp_win}_N) \times (\text{CLHWM} - X) / \text{CLHWM} + (\text{clamp_win}_{i+1} - \text{clamp_win}_N) \times X / \text{CLHWM}$
6. If the valid pixel is on the left of the center of the left-most window, the clamp value of the left-most window is applied. If the valid pixel is on the right of the center of the right-most window, the clamp value of the right-most window is applied.

The clamp values calculated (A), (B), and (C) are:

- Case1: Base is win_0 (Left-most window: `ISIF_CLHWIN0[5]` CLHWBS = 0x0)
 - (A): zero
 - (B): $(\text{clamp_win}_{i+1} - \text{clamp_win}_i) \times X / \text{CLHWM}$
 - (C): $(\text{clamp_win}_N - \text{clamp_win}_0)$
- Case2: Base is win_N (Right-most window: `ISIF_CLHWIN0[5]` CLHWBS = 0x1)
 - (A): $(\text{clamp_win}_0 - \text{clamp_win}_N)$
 - (B): $(\text{clamp_win}_i - \text{clamp_win}_N) \times (\text{CLHWM} - X) / \text{CLHWM} + (\text{clamp_win}_{i+1} - \text{clamp_win}_N) \times X / \text{CLHWM}$
 - (C): zero

Each interpolated value $\text{interpolated_clamp_win}_x$ is then subtracted to the associated column.

9.3.3.9.8.2 ISS ISP ISIF Clamp Value for Vertical Direction

The clamp value for vertical direction is calculated using the pixel values at the left or right OB region. Line average is calculated for the OB H valid period ($2^{(\text{ISIF_CLVWIN0}[2:0] \text{ CLVOBH} + 1)}$). The averages for the previous lines are also added back to reduce the difference between the lines, as shown in Figure 9-149.

Figure 9-149. ISS ISP ISIF Clamp Value for Vertical Direction Calculation

camss-619

- Clamp Value (V_n) = Line Average (V_n) * k + Clamp Value (V_1) * (1-k)
- $k = \text{ISIF_CLVWIN0}[15:8] \text{ CLVCOEF}$

The position of the first vertical black clamp window is set with the `ISIF_CLVWIN2[12:0]` CLVSV and `ISIF_CLVWIN1[12:0]` CLVSH bit fields. The number of vertical windows is set with the `ISIF_CLVWIN3[12:0]` CLVOBV bit field. `ISIF_VDW` sets the width of the VD.

The accumulator, which holds the vertical clamp value for the previous line, is reset at the beginning of the OB V valid. The reset value can be selected through the `ISIF_CLVWIN0[5:4]` CLVRVSL bit field:

- `ISIF_CLVWIN0[5:4]` CLVRVSL = 0x0: The base value is calculated for horizontal direction (left-most window win_0 or right-most win_n set with `ISIF_CLHWIN0[5]` CLHWBS).
- `ISIF_CLVWIN0[5:4]` CLVRVSL = 0x1: The base value is set through the configuration register (`ISIF_CLVRV[11:0]` CLVRV).
- `ISIF_CLVWIN0[5:4]` CLVRVSL = 0x2: No update (same as the previous image)

The following figures show the OB valid settings and associated vertical clamp value calculation when OB region is at the left (see Figure 9-150) and when OB region is at the right (see Figure 9-151). Each line average value is subtracted from the associated line valid region data.

Figure 9-150. ISS ISP ISIF Clamp Value for Vertical Direction With OB Region at the Left

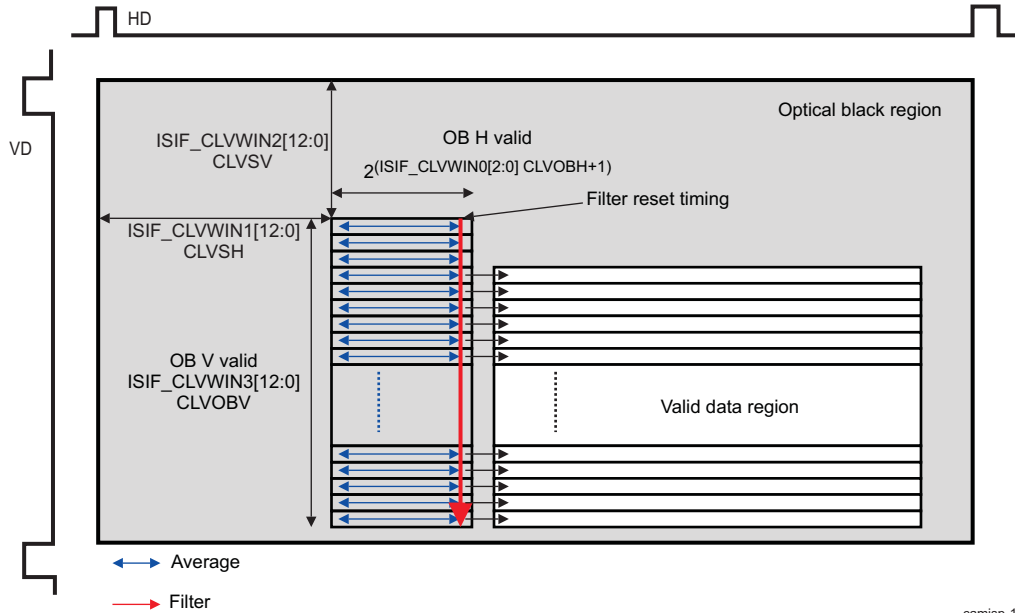

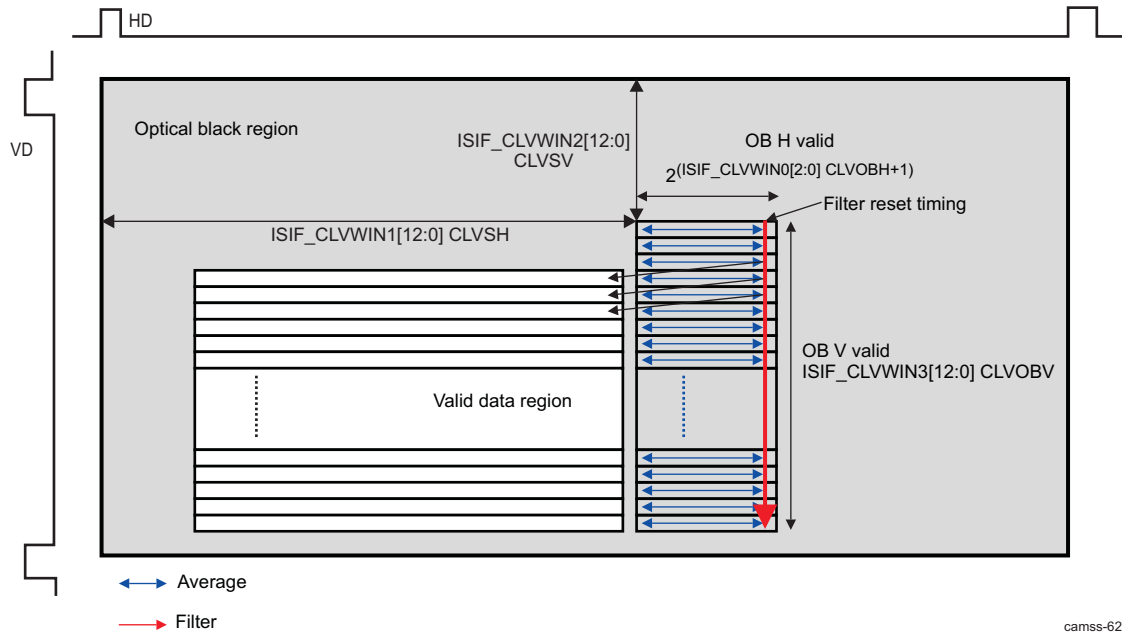

Figure 9-151. ISS ISP ISIF Clamp Value for Vertical Direction With OB Region at the Right

9.3.3.9.9 ISS ISP ISIF Vertical Line Defect Correction (VDFC)

Figure 9-152 shows the block diagram of the vertical line defect (VDFC) correction.

Figure 9-152. ISS ISP ISIF Vertical Line Defect Correction Block Diagram

The VDFC block can correct up to eight vertical line defects (see Figure 9-153).

Figure 9-153. ISS ISP ISIF Vertical Line Defects

The correction method is common to all the defects and can be selected through the `ISIF_DFCCTL[6:5]` `VDFCSL` bit field.

There are two different methods to correct vertical line defects (`ISIF_DFCCTL[6:5]` `VDFCSL`):

- Method 1: Data is replaced by an average (`ISIF_DFCCTL[6:5]` `VDFCSL` = 0x2):
 - The defect is replaced by the average of pixel (i - 2) and pixel (i + 2).
- Method 2: Data is subtracted by a defect level (`ISIF_DFCCTL[6:5]` `VDFCSL` = 0x0 or 0x1):
 - A saturation level is defined in the `ISIF_VDFSATLV[11:0]` `VDFSLV` bit field.
 - The coordinates of the defect:
 - Are defined in the `ISIF_DFCMEM0[12:0]` `DFCMEM0` and `ISIF_DFCMEM1[12:0]` `DFCMEM1` bit fields
 - Are 13 bits wide for horizontal and vertical direction, so an image size up to 8192 × 8192 is supported
 - If the data is not saturated (data < `VDFSLV`):
 - The defect is corrected by subtracting the defect level. A different defect level is defined for:
 - The point of the defect (V = `Vdefect`): `SUB1` defect level is defined in the `ISIF_DFCMEM2[7:0]` `DFCMEM2` bit field.
 - The pixels lower than the defect (V < `Vdefect`): `SUB2` defect level is defined in the `ISIF_DFCMEM3[7:0]` `DFCMEM3` bit field.
 - The pixels above the defect (V > `Vdefect`): Defect level is defined in the `ISIF_DFCMEM4[7:0]` `DFCMEM4` bit field.
 - Each defect level (value to be subtracted from the data) described previously can be up-shifted through the `ISIF_DFCCTL[10:8]` `VDFLSFT` bit field.
 - Vertical line defect correction for upper pixels can be disabled through the `ISIF_DFCCTL[7]` `VDFCUDA` bit.
 - If the data is saturated (`VDFSLV`), there are two possibilities:
 - `ISIF_DFCCTL[6:5]` `VDFCSL` = 0x0: Data is simply fed through (not subtracted).
 - `ISIF_DFCCTL[6:5]` `VDFCSL` = 0x1: Horizontal interpolation $((i - 2) + (i + 2)) / 2$ (data is replaced

by interpolation or data is subtracted with interpolation)

The [ISIF_LPFR](#) register sets the number of half lines per frame or field: $VD \text{ period} = (L \text{ PFR} + 1) / 2 \text{ lines}$. LPFR is not used when HD and VD are inputs.

The following paragraphs concern only method 2 correction.

The coordinates of the defects and the defect levels to be subtracted from the data must be set to the processing listed in [Table 9-242](#).

Table 9-242. ISS ISP ISIF Vertical Line Defect Table in Memory

Bit	Defect Information
12:0	Vertical position of the defects
25:13	Horizontal position of the defects
33:26	Defect level of the vertical line defect position ($V = V_{\text{defect}}$)
41:34	Defect level of the pixels above the vertical line defect ($V < V_{\text{defect}}$)
49:42	Defect level of the pixels below the vertical line defect ($V > V_{\text{defect}}$)

The defect must be set from left to right, as shown in [Figure 9-154](#).

Figure 9-154. ISS ISP ISIF Vertical Line Defects

camisp-135

Vertical line defect correction is enable by setting the [ISIF_DFCCTL\[4\]](#) VDFCEN bit to 1, but the procedure in [Section 9.3.3.9.9.1, ISS ISP ISIF Vertical Line Defect Table Update Procedure](#), must be followed.

9.3.3.9.9.1 ISS ISP ISIF Vertical Line Defect Table Update Procedure

This procedure must be followed to write the vertical line defect table in memory.

1. [ISIF_DFCMEMCTL\[4\]](#) DFCMCLR = 0x1
2. Ensure that [ISIF_DFCCTL\[4\]](#) VDFCEN is disabled (0x0).
3. Write the V coordinate of the first defect to the [ISIF_DFCMEM0\[12:0\]](#) DFCMEM0 bit field.
4. Write the H coordinate of the first defect to the [ISIF_DFCMEM1\[12:0\]](#) DFCMEM1 bit field.
5. Set the defect level to:
 - [ISIF_DFCMEM2\[7:0\]](#) DFCMEM2
 - [ISIF_DFCMEM3\[7:0\]](#) DFCMEM3
 - [ISIF_DFCMEM4\[7:0\]](#) DFCMEM4
6. Set the [ISIF_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF_DFCMEMCTL\[2\]](#) DFCMARST bit set to 1.
7. Wait until the [ISIF_DFCMEMCTL\[0\]](#) DFCMWR bit is cleared.
8. Write the next data to:
 - [ISIF_DFCMEM0\[12:0\]](#) DFCMEM0

- [ISIF_DFCMEM1\[12:0\]](#) DFCMEM1
 - [ISIF_DFCMEM2\[7:0\]](#) DFCMEM2
 - [ISIF_DFCMEM3\[7:0\]](#) DFCMEM3
 - [ISIF_DFCMEM4\[7:0\]](#) DFCMEM4
9. Set the [ISIF_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF_DFCMEMCTL\[2\]](#) DFCMARST bit cleared.
 10. Repeat four or five times until all entries (up to eight) are written to the vertical line defect table.
 11. If the defect entry is less than eight, an extra write cycle is required to fill the next table location with a certain value.
 12. Clear the [ISIF_DFCMEM0\[12:0\]](#) DFCMEM0 bit field to all 0's, set the [ISIF_DFCMEM1\[12:0\]](#) DFCMEM1 to all 1's, and set the [ISIF_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF_DFCMEMCTL\[2\]](#) DFCMARST bit cleared.
 13. Enable VDFC by setting the [ISIF_DFCCTL\[1\]](#) VDFCEN bit.

9.3.3.9.10 ISS ISP ISIF Lens Shading Correction Module (2D-LSC)

NOTE: For the memory access locations of the 2D-LSC table, see [Section 9.3.3.11, ISS ISP Memory Mapping](#).

Figure 9-155. ISS ISP ISIF 2D-LSC Block Diagram

Lens shading correction (LSC) is useful for correcting optical artifacts that cause image brightness to decrease starting at the center of the image and going to the edges.

The LSC implements a per-pixel offset and gain adjustment in the RAW Bayer domain (2 × 2 color pattern).

- In 8-bit gain mode, when the [ISIF_2DLSCCFG\[6\]](#) GAIN_RANGE bit is set to 0, the offset is applied before gain multiplication.
- In 16-bit gain mode, when the [ISIF_2DLSCCFG\[6\]](#) GAIN_RANGE bit is set to 1, the offset function is disabled, and the loaded offset value is used to constitute the lower 8 bits of the 16-bit gain table offset table.

The offset and gains are stored in a LUT, which is stored in SDRAM and is loaded in real time. The submodule prefetches the data from SDRAM such that no underflow occurs. Underflow occurs when the offset and gain data required for the current pixel are not available.

The data stored in the LUT is downsampled; that is, there is no gain or offset per pixel. The downsampling factor is programmable. High downsampling ratios lead to a smaller LUT, lower accuracy, and lower memory bandwidth. A low downsampling ratio leads to a bigger LUT, higher accuracy, and higher memory bandwidth.

When the offset and gain values are loaded, they are upscaled to the incoming image resolution. The missing table values are computed through bilinear interpolation.

To enable the 2D-LSC module, set the [ISIF_2DLSCCFG\[0\]](#) ENABLE bit to 1.

9.3.3.9.10.1 ISS ISP ISIF 2D-LSC Active Region Settings

The gain and offset maps are internally upsampled to full resolution before being applied to the image. To account for all the possible cropping schemes and zoom ratios, the 2D-LSC can be configured to store a single gain map in memory that maps to sensor lens. [Figure 9-156](#) shows the 2D-LSC active region.

Figure 9-156. ISS ISP ISIF 2D-LSC Active Region for ISIF Input Frame

camss-621

9.3.3.9.10.1.1 ISS ISP ISIF 2D-LSC Gain and Offset Tables

The gain and offset map are $M \times N$ downsampled:

- M is the horizontal sampling factor.
- N is the vertical sampling factor.
- M and N are $\{8, 16, 32, 64, 128\}$ independently.
- $N = M$. M is set in the [ISIF_2DLSCCFG\[14:12\]](#) GAIN_MODE_M bit field.
- N is set in the [ISIF_2DLSCCFG\[10:8\]](#) GAIN_MODE_N bit field.

The starting point of the preconfigured lens shading map can be modified in software to align with the ISIF input image frame. The location of the gain and offset mask data in memory is specified as follows:

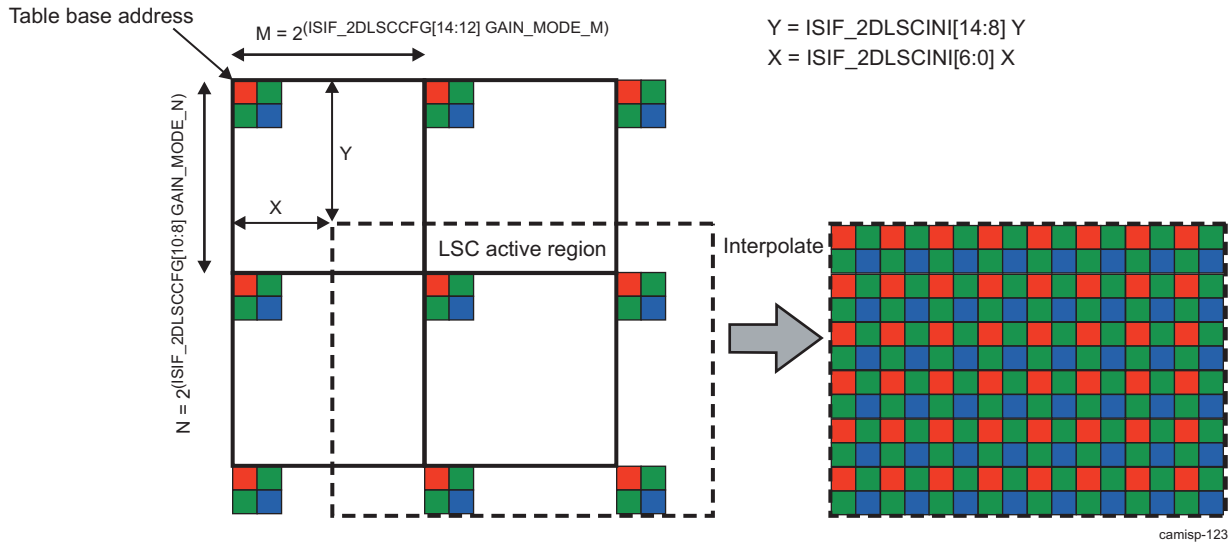

- For gain map:
 - Table base address: [ISIF_2DLSCGRBU\[15:0\]](#) BASE31_16 and [ISIF_2DLSCGRBL\[15:0\]](#) BASE15_0
- For offset map:
 - Table base address: [ISIF_2DLSCORBU\[15:0\]](#) BASE and [ISIF_2DLSCORBL\[15:0\]](#) BASE

The input address must be aligned to a 4-byte boundary.

In the full resolution case, the address is set to the beginning of the map. When the LSC active region is defined over a cropped region of the full image, the SDRAM input address can be set to the upper-left corner of the grid closest to the beginning of the active region, and the [ISIF_2DLSCINI\[6:0\]](#) X and [ISIF_2DLSCINI\[14:8\]](#) Y bit fields mark the offset into the upsampled gain and offset map where the active region begins. [Figure 9-157](#) shows the LSC active region with respect to the gain and offset map grid. Because (X, Y) deals with the pixel phase inside a gain and offset map grid, X and Y must each be less than M and N , respectively.

Before applying the gain or offset table, the table is internally upsampled and interpolated back to full resolution via bilinear interpolation.

Figure 9-157. ISS ISP ISIF Gain and Offset Mask Upsampling via Bilinear Interpolation

The gain table format is set in the [ISIF_2DLSCCFG\[4:1\] GAIN_FORMAT](#) bit field. Eight-bit entries are supported in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with an optional base of 1.0 to shift the range up).

Eight-bit entries are supported in the offset map (in S8Q0 format). An optional shifting up for offsets is possible. The shift-up value is selected through the [ISIF_2DLSCOFST\[6:4\] OFSTSFT](#) bit field. A scaling factor for offsets is defined in the [ISIF_2DLSCOFST\[15:8\] OFSTS](#) bit field.

A 16-bit gain map is supported by combining the gain map and offset map (in U16Q16, U16Q15, U16Q14, U16Q13, U16Q12, U16Q11, U16Q10, and U16Q9 format with an optional base of 1.0 to shift the range up). This function is exclusive to offset control function, and can be configured through the [ISIF_2DLSCCFG\[6\] GAIN_RANGE](#) bit.

The offset control in the 2D-LSC module can be enabled or disabled through the [ISIF_2DLSCOFST\[0\] OFSTEN](#) bit.

For an LSC active region size of $W \times H$ (the output and input are the same size), and the gain and offset maps are $M \times N$ downsampled, a table with the following values is needed:

- $(\text{ceil}[(X + W) / M] + 1) \times (\text{ceil}[(Y + H) / N] + 1) \times 4$ bytes data in external memory organized as:
 - $(\text{ceil}[(\text{InitX} + W) / M] + 1)$ lines of data
 - Each line having at least $(\text{ceil}[(\text{InitY} + H) / N] + 1) \times 4$ data points

Extra data at end of each line can be skipped by the line offset register parameter:

- For gain map:
 - Line offset: [ISIF_2DLSCGROF\[15:0\] OFFSET](#)
- For offset map:
 - Line offset: [ISIF_2DLSCOROF\[15:0\] OFFSET](#)
- Each line offset must start at a 32-bit aligned boundary.

9.3.3.9.10.1.2 ISS ISP ISIF 2D-LSC Gain and Offset Table Upsampling

Upsampling of the pixel-by-pixel gains is performed by locating the four same-color anchors for each destination gain value and applying bilinear interpolation.

The gain and offset mask function is neutral to color pattern. The starting color of the gain and offset mask must be consistent with the starting color of the image, and can be any color. To align starting colors, the X and Y values must be even. The 2D-LSC engine upsamples each phase of the mask data as a separate plane and applies the upsampled mask to the image with the same color phasing. In other words, the red gains are interpolated with red gains, and applied to the red input pixels. The same process is done for the other three colors in the color pattern. The 2D-LSC module is designed to work with Bayer CFA data, having the R/Gr/Gb/B color pattern. For the purpose of functional description, assume red is the starting color, but any other starting color or other 2 x 2 pattern can be used by placing color gains in the appropriate order.

9.3.3.9.10.1.3 ISS ISP ISIF Application of Gain and Offset to Image Pixels

The gain value interpolated for each pixel is multiplied with a corresponding input pixel. An offset is applied before the gain. The product is rounded to the nearest integer and then clipped or saturated to the valid range of 13 bits.

The following equation describes the operation of the LSC in terms of offset and gain:

$$\text{out}[x,y] = (\text{in}[x,y] + a \times (\text{ofst}[x,y] \ll T)) \times \text{gain}[x,y] \quad (3)$$

- in[x, y] are the input pixels, 13 bits signed.
- ofst[x, y] are the upsampled offset points.
- T is the upshift value applied to the result of the offset interpolation points (0–5) set through the [ISIF_2DLSCOFST\[6:4\]](#) OFSTSFT bit field.
- a is the offset gain value in U8Q7 format set through the [ISIF_2DLSCOFST\[15:8\]](#) OFSTSF bit field.
- gain[x, y] are the upsampled gain points.
- out[x, y] are the resulting output pixels, 13 bits signed.

9.3.3.9.10.1.4 ISS ISP ISIF Enabling and Disabling the 2D-LSC Module

LSC operates on a single frame or continuously, depending on the firmware programming.

Upon power-on reset (POR), the 2D-LSC module is disabled and input pixels are copied to the output, thus bypassing any shading operation.

When enabling or disabling the 2D-LSC, caution must be taken on the timing of register modifications. To avoid causing a prefetch error or other unexpected behavior, the following safeguards must be implemented:

1. While configuring the 2D-LSC registers, the input clock into the ISIF should be toggling.
2. All of the 2D-LSC registers must be configured appropriately before enabling the [ISIF_2DLSCCFG\[0\]](#) ENABLE bit.
3. After setting the ENABLE bit to 1, the hardware immediately begins fetching the first two rows of gain and offset data entries from external memory. When this is complete, the [ISIF_2DLSCIRQST\[2\]](#) PREFETCH_COMPETED status flag is set.

NOTE: If the ENABLE bit is disabled before the [ISIF_2DLSCIRQST\[3\]](#) SOF status flag is set, the [ISIF_2DLSCIRQST\[1\]](#) PREFETCH_ERROR flag is set and the state of the 2D-LSC module may lead to unexpected errors. Therefore, the ENABLE bit must not be disabled until after the [ISIF_2DLSCIRQST\[3\]](#) SOF status flag is set.

4. Appropriate gains and offsets are applied to the image pixels. Pixels outside the LSC active region are passed through unaltered. When the 2D-LSC operation on the active region completes, the [ISIF_2DLSCIRQST\[0\]](#) DONE status flag is set.
5. At this point:
 - If the ENABLE bit is still set to 1, the hardware immediately begins to prefetch the gain and offset data entries for the next frame and waits for the active region of the next frame to arrive.
 - If the ENABLE bit is set to 0, it stops LSC operation once the active region is passed, and goes into idle mode until the ENABLE bit is reset to 1.

NOTE: To provide a mechanism for firmware to recover from the LSC module waiting indefinitely for the input image, if the LSC_ENABLE bit is set to 0 after it has started gain/offset map prefetching, but before the LSC gets to the next active region, the LSC operation is aborted and turned idle, and any prefetched gain/offset entries are discarded. This can happen before or after the next start-of-frame.

NOTE: Therefore, because of the constraints set in point 3, the ENABLE bit must be disabled only after the [ISIF_2DLSCIRQST\[3\]](#) SOF status flag is set and before the [ISIF_2DLSCIRQST\[0\]](#) DONE status flag is set for that same frame.

It is suggested that when the 2D-LSC or the whole ISIF must be disabled for switching modes, the [ISIF_2DLSCIRQST\[3\]](#) SOF interrupt be enabled so that software knows when it is safe to disable the 2D-LSC. Then the ISIF can be disabled after the [ISIF_2DLSCIRQST\[0\]](#) DONE status signal is set for that frame.

NOTE: The LSC_ENABLE bit, once set to 1, must not be cleared until at least one vpi_clk clock cycle after start-of-frame, to ensure correct processing.

9.3.3.9.10.1.5 ISS ISP ISIF 2D-LSC Events and Status Checking

The 2D-LSC module can generate events on a single interrupt line. These events are further remapped at the ISP level in the ISP5_IRQENABLE_SET_i[3] ISIF_INT_3 bit, where i = 0 to 3.

Four 2D-LSC events can be generated:

- **DONE:** LSC done. This event triggers when the LSC submodules transition from ACTIVE state to IDLE state.
- **PREFETCH_ERROR:** Gain table prefetch error. This event triggers when the tables stored in SDRAM are read too slowly. After this event is asserted, the LSC disables the LSC computation until the beginning of the next frame.
- **PREFETCH_COMPLETE:** Gain table prefetch complete. This event triggers when data prefetching from SDRAM completes. Data prefetching must complete by the time the first pixel of a frame arrives. The event triggers when the buffer contains three full rows of data.
- **SOF:** This event signals the start of the LSC valid region. The LSC configuration registers for the next frame can be updated after the LSC SOF triggers.

The [ISIF_2DLSCIRQEN](#) register can be configured to select which events are masked and which are propagated to the LSC interrupt signal. The [ISIF_2DLSCIRQST](#) register can be read and cleared to identify which events have occurred.

In addition, the 2D-LSC module provides the following status bit:

- **BUSY:** This indicates that LSC has entered the active region vertically. This bit remains on during horizontal blanking, and turns off only after the entire active region of the current frame is processed.

9.3.3.9.10.1.6 ISS ISP ISIF Supported On-the-Fly 2D-LSC Configurations

The 2D-LSC prefetch memory is equal to $2 \times 1536 \times 32$ bits. This memory is sized to fetch three lines of 8-bit gain and 8-bit offset \times four color components per paxel. Given an image sensor of horizontal resolution H, there are $\text{floor}[(H / \text{ISIF_2DLSCCFG}[14:12] \text{ GAIN_MODE_M}) + 1]$ paxels per line, where M is the horizontal LSC paxel size.

[Table 9-243](#) shows the LSC horizontal paxel size, which can be supported for different image sensor resolutions. When M = 8, some resolutions cannot be supported on the fly (orange-shaded cells in the table); the way to process such large images is to use vertical frame division.

Table 9-243. ISS ISP ISIF Supported On-the-Fly LSC Configurations

MPix	Aspect Ratio		Line Size	Horizontal LSC Poxel Size: $M = 2^{\text{ISIF_2DLSCCFG}[14:12] \text{ GAIN_MODE_M}}$				
				8	16	32	64	128

9.3.3.9.10.1.7 ISS ISP ISIF Bandwidth Requirements on BL Read Port

For details, see [Section 9.3.3.9.19.2, ISS ISP ISIF Read Port.](#)

9.3.3.9.11 ISS ISP ISIF White Balance

Figure 9-158 shows the white balance block diagram.

Figure 9-158. ISS ISP ISIF White Balance Block Diagram

Color pattern settings are set through the [ISIF_CCOLP](#) register. Moreover, through this register the pixel position from 0 to 3 can be set to the needed Bayer universal camera filter color pattern (RGB/CYGM).

The CFA pattern can be in two modes, stripe or mosaic, and is set through the [ISIF_CGAMMAWD\[5\]](#) CFAP bit.

There are color-dependent gain controls for the three outputs:

- BL output
- IPIPEIF (IPIPE path) output

- IPIPEIF (H3A path) output

The gain applied to each data is selected according to the pixel position and the color pattern settings. Gain factors are common for the three data paths. Gain is in U11Q9 format, which ranges from 0 to 3 + 511/512. The gain factor is set through the following registers:

- R/Ye gain: [ISIF_CRGAIN\[11:0\]](#) CGR
- Gr/Cy gain: [ISIF_CGRGAIN\[11:0\]](#) CGGR
- Gb/Cy gain: [ISIF_CGBGAIN\[11:0\]](#) CGGB
- B/Mg gain: [ISIF_CBGAIN\[11:0\]](#) CGB

Gain control can be enabled or disabled individually for each path.

- Enable or disable gain for the BL path: [ISIF_CGAMMAWD\[12\]](#) WBEN0
- Enable or disable gain for the IPIPEIF (IPIPE) path: [ISIF_CGAMMAWD\[13\]](#) WBEN1
- Enable or disable gain for the IPIPEIF (H3A) path: [ISIF_CGAMMAWD\[14\]](#) WBEN2

After the gain control, a single offset value can be added to each path individually. This offset is common for the three paths and is set through the [ISIF_COFSTA\[11:0\]](#) COFT bit field. The offset value is U12, which ranges from 0 to 4095. Data (S13) are then truncated to U12.

- Enable or disable offset for the BL path: [ISIF_CGAMMAWD\[8\]](#) OFSTEN0
- Enable or disable offset for the IPIPEIF (IPIPE) path: [ISIF_CGAMMAWD\[9\]](#) OFSTEN1
- Enable or disable offset for the IPIPEIF (H3A) path: [ISIF_CGAMMAWD\[10\]](#) OFSTEN2

9.3.3.9.12 ISS ISP ISIF Low-Pass Filter

Figure 9-159 shows the low-pass filter (LPF) block diagram.

Figure 9-159. ISS ISP ISIF Low-Pass Filter Block Diagram

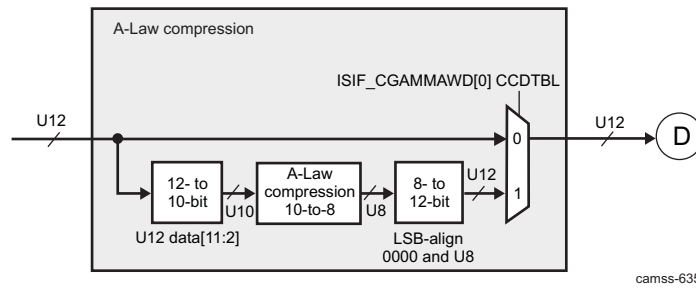

An optional horizontal low-pass anti-aliasing filter (LPF) can be applied (the [ISIF_MODESET\[14\]](#) HLPF bit) after reframing. The LPF consists of a simple 3-tap (1/4, 1/2, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

NOTE: For YUV data, the LPF must be disabled ([ISIF_MODESET\[14\]](#) HLPF = 0x0).

9.3.3.9.13 ISS ISP ISIF A-Law Compression

Figure 9-160 shows the A-Law compression block diagram.

Figure 9-160. ISS ISP ISIF A-Law Compression Block Diagram

An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied (the [ISIF_CGAMMAWD\[0\] CCDTBL](#) bit) as the final processing stage. Using this compression causes the data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected (the [ISIF_CGAMMAWD\[4:1\]](#) GWDI bit field).

The IPIPEIF module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

NOTE: Do not use A-Law compression ([ISIF_CGAMMAWD\[0\] CCDTBL](#) = 0) with YUV data.

[Figure 9-161](#) shows the A-Law table diagram, and [Figure 9-162](#) shows the A-Law table values.

Figure 9-161. ISS ISP ISIF A-Law Table Diagram

Figure 9-162. ISS ISP ISIF A-Law Table Values

Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law

9.3.3.9.14 ISS ISP ISIF Culling

Figure 9-163 shows the culling block diagram.

Figure 9-163. ISS ISP ISIF Culling Block Diagram

The culling block performs a programmable decimation function for horizontal, vertical, and YUV4:2:2 data directions. The horizontal and vertical decimation of image data can be controlled by two registers.

The horizontal culling operation allows selected pixel data to be culled (deleted) from a line. The **ISIF_CULH** register specifies the horizontal culling pattern for even and odd lines:

- Even lines: **ISIF_CULH**[15:8] CLHE
- Odd lines: **ISIF_CULH**[16:0] CLHO

The vertical culling operation allows selected lines to be culled from a frame. The **ISIF_CULV** register specifies the pattern for the vertical direction. The LSBs of CULV represent the top line of the CCD; the MSB is the seventh line. For proper operation, LSB of CULV must be always 1 (**ISIF_CULV**[7:0]=1).

Figure 9-164 is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, **CULH** = 0x59C4 and **CULV** = 0x0066.

NOTE: Culling can be used with YUV data, but care must be taken to preserve the YUV4:2:2 output format.

Figure 9-164. ISS ISP ISIF Example for Decimation Pattern

9.3.3.9.15 ISS ISP ISIF 12-to-8-Bit DPCM Compression Block

In the ISIF, a DPCM compression block is between the culling module and the storage formatter module. This block can compress 12-bit image data to 8 bits for bandwidth reduction in transmission between the ISIF and SDRAM. An 8-to-12-bit DPCM decoder at the IPIPEIF decompresses data for IPIPE processing.

Two different predictors are used for the compression system. The first predictor is simple (simple predictor), and the second predictor is slightly more complex (advanced predictor). Because the advanced predictor gives a slightly better prediction for the pixel value, the image quality can be improved using it. Because the simple predictor is very basic, the processing power and memory requirements are reduced using it, when the image quality is already sufficiently high.

- Advanced predictor: This predictor uses only the previous same color component value as a prediction value. Therefore, only 2-pixel memory is required.
- This predictor uses four previous pixel values when the prediction value is evaluated. This means that the other color component values are also used when the prediction value is defined.

The function is controlled from the [ISIF_MISC\[12\] DPCMEN](#) and [ISIF_MISC\[13\] DPCMPRE](#) bits.

9.3.3.9.16 ISP ISIF Storage Formatter

[Figure 9-165](#) shows the storage formatter block diagram.

Figure 9-165. ISS ISP ISIF Storage Formatter Block Diagram

Data are stored to the lower bits of a 16-bit SDRAM word, or can be 8- or 12-bit packed. The [ISIF_HSIZE\[11:0\]](#) HSIZE bit field can specify the memory address offsets between lines of memory (offset in 32-byte units). If set, the [ISIF_HSIZE\[12\]](#) ADCR bit can decrement the memory address line and the line can be horizontally flipped in memory.

In case of RAW data, a data shift module is used: data to be stored can be right-shifted according to the value set at the [ISIF_MODESET\[10:8\]](#) CCDW bit field, as described in [Table 9-244](#).

Table 9-244. ISS ISP ISIF RAW Data Shifting

ISIF_MODESET[10:8] CCDW	Output Format
	MSB LSB
000	0000 &U12 data[11:0]
001	00000 &U12 data[11:1]
010	000000 &U12 data[11:2]
011	0000000 &U12 data[11:3]
100	00000000 &U12 data[11:4]

Table 9-245 shows the format where data are stored to the lower bits of a 16-bit word and the format where data are packed to 8 bits. The unused bits are filled with zeros.

Table 9-245. ISS ISP ISIF SDRAM Data Format

	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
12 bit	0	Pixel 1	0	Pixel 0
11 bit	0	Pixel 1	0	Pixel 0
10 bit	0	Pixel 1	0	Pixel 0
9 bit	0	Pixel 1	0	Pixel 0
8 bit	0	Pixel 1	0	Pixel 0
8-bit packed	Pixel 3	Pixel 2	Pixel 1	Pixel 0

Table 9-246 shows the format where data are packed to 12 bits.

Table 9-246. ISS ISP ISIF SDRAM Data Format for 12-bit Packed

	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
12 bit	Pixel2[7:0]	Pixel1	Pixel 0	
	Pixel5[3:0]	Pixel4	Pixel3	Pixel2[11:8]
	Pixel7	Pixel6	Pixel5[11:4]	

In case of YUV, YUV data is stored in memory in packed YUV4:2:2 mode, using 2 pixels per 32 bits, as shown in [Table 9-247](#).

The output formatter can configure to any image format by using the SDRAM line offset register and offset control registers. [Figure 9-166](#) shows how to construct a frame format in SDRAM. The `ISIF_CADU[10:0]` CADU bit field specifies the memory destination (upper 11 bits) to SDRAM (the address is the value of the set bit multiplied by 32 bytes). On the other hand, the `ISIF_CADL[15:0]` CADL bit field sets the memory destination to SDRAM (lower 16 bits) (the address is the value of the set bit multiplied by 32 bytes).

- `ISIF_SPH` defines the first pixel in a line to be stored to memory.
- `ISIF_LNH` defines the number of pixels in an line to be stored to memory.
- `ISIF_LNV` defines the number of lines to be stored to memory.
- `ISIF_SLV0` sets line at which data output to SDRAM will begin.
- `ISIF_SLV1` sets line at which data output to SDRAM will begin, measured from the start of VD.
- `ISIF_SDOFST`, `ISIF_MODESET[15]` MDFS, and `ISIF_MODESET[4]` FIPOL sets the setting for line FID polarity and the offset of even/odd lines in SDRAM.

Figure 9-166. ISS ISP ISIF Frame Image Format Conversion

camisp-125

9.3.3.9.17 ISS ISP ISIF Circular Buffer

In addition to the [Section 9.3.3.9.16](#), ISIF support circular buffer addressing. [Figure 9-167](#) shows this circular buffer function.

Figure 9-167. ISS ISP ISIF Circular Buffer control

camisp-808

1. The write address starts from the start address (SAD), specified by the `ISIF_CADU` and `ISIF_CADL` registers.

$$\text{SAD} = (\text{ISIF_CADU} \ll 21) + (\text{ISIF_CADL} \ll 5)$$
 If field offset is enabled, field offset (FOFST: `ISIF_SDOFST[13:12]` FOFST) value may be added to this value

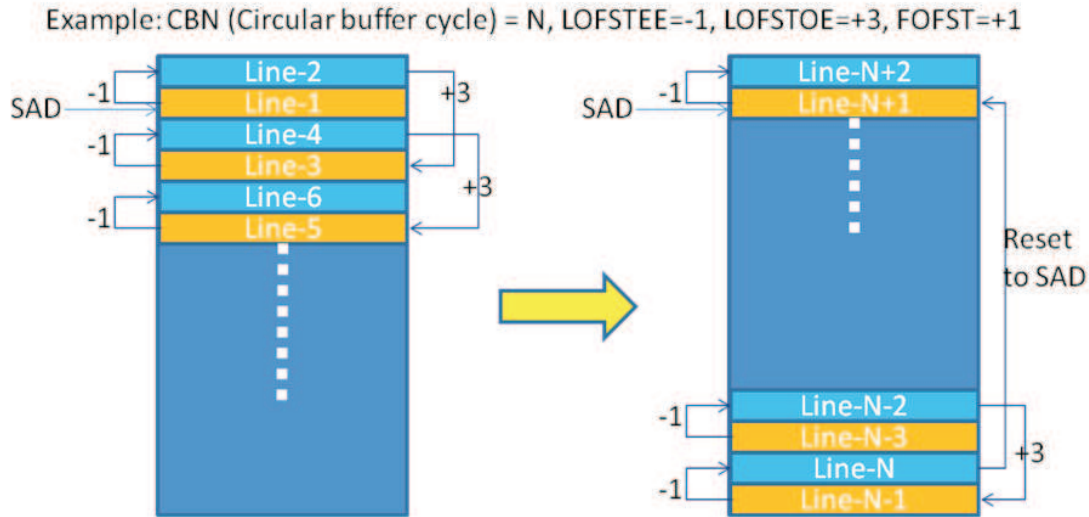

$$\text{SAD} = (\text{ISIF_CADU} \ll 21) + (\text{ISIF_CADL} \ll 5) + \text{ISIF_SDOFST}[13:12] \text{ FOFST}$$
2. After each line is written to the SDRAM, the address pointer moves to the first address of the next line. For example, if the line offset (LOFSTxx) is all +1, the first address of each line is:
 Address (0 line) = SAD
 Address (1st line) = SAD + HSIZE
 Address (2nd line) = SAD + HSIZE x 2
 ...
 (If the line offset is not +1, the address change will be in the way specified in [Figure 9-166](#))
3. This process continues until the number of output lines reaches CBN lines.
4. When CBN-th line is complete, the address goes back to SAD Restart counting the number of lines from 1.
5. Repeat 2 to 4, until all output lines are written to memory.
 If CBN=0, the circular buffer function is not used. The memory address is used as a linear space, and does not go back to the start address at CBN-th line.

Circular buffer function can be used in combination with Output Formatter. Since Output Formatter allows the line offset to be -4 to +4 lines, the address may go earlier than SAD after reset. SW should make sure to allocate memories for such case. See [Figure 9-168](#)

For circular buffer to work effectively, interrupt is available. After every CYN lines, an interrupt (isif_cb) is issued. This notifies how many lines in the circular buffer is filled.

NOTE: This event (isif_cb) is also exposed to ICM, and ICM can use this as P_DONE. However, ISIF does not implement ICM handshake, and does not receive P_START signal.

Figure 9-168. ISS ISP ISIF Combination of Circular Buffer and Output Formatter

When used with Output Formatter, the address is reset to SAD when the number of lines reaches CBN

camisp-809

9.3.3.9.18 ISS ISP ISIF YCbCr Signal Processing

The ISIF accepts 4:2:2 sampled YCbCr input data. The Luma and color difference signals are 8 bits each, scaled 0 to 255. The color difference signals are multiplexed into one 8-bit bus beginning with a Cb sample. The Y and CbCr buses can be input parallel (16-bit mode) or time-multiplexed and input as a single bus (8-bit mode).

The 16- or 8-bit YCbCr data is stored in SDRAM as 4:2:2 format. [Table 9-247](#) lists the data format in SDRAM. Y data typically has a range of 16 to 235; however, it is possible to subtract a DC value from the Y signal.

Table 9-247. ISS ISP ISIF Memory Output Format for YUV Data

Memory Address	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

9.3.3.9.19 ISS ISP ISIF Expected Bandwidth on BL Ports

The ISIF has a write port and a read port connected to the BL. This section summarizes the expected bandwidth on these ports.

9.3.3.9.19.1 ISS ISP ISIF Write Port

The write port is used to write pixels to memory after the data have passed through the storage formatter. Data storage to SDRAM is controlled by the `ISIF_SYNCEN[1]` DWEN bit. The ISIF allows writing the data as 16, 12, and 8 bpp. The bit width is controlled by the `ISIF_CCDCFG[1:0]` SDRPACK bit field.

The write port generates a burst of 32 bytes on the MTC interface. The delay between consecutive bursts is proportional to the input pixel clock. Hence, the write port does not request peak bandwidth traffic.

[Table 9-248](#) lists the estimated delay between 32-byte MTC requests for different pixel clock frequencies and assumes the L3_MAIN clock is 212.8 MHz.

Table 9-248. ISP ISIF ISIF Module: Write Port Bandwidth

Pixel Clock	Maximum Bandwidth 2 Bytes/s Pixel MB/s	Expected Delay Between MTC Requests
212.8	400	16 cycles = 80 ns
100	200	32 cycles = 160 ns
10	20	320 cycles = 1600 ns

9.3.3.9.19.2 ISS ISP ISIF Read Port

The read port is used to read gain and offset data from SDRAM required for the LSC computation. When LSC is enabled, 8-bit gain values are read and 8-bit offset values can optionally also be read. The LSC gain computation can be enabled or disabled by setting the `ISIF_2DLSCCFG[0]` ENABLE bit. The LSC offset computation can be enabled by setting the `ISIF_2DLSCOFST[0]` OFSTEN bit.

LSC fetches four 8-bit gain values per paxel and optionally four 8-bit offset values per paxel. This is a maximum 8 bytes per paxel.

The bandwidth that is generated by the LSC module is also proportional to the paxel size. The paxel size is set up by the `ISIF_2DLSCCFG[14:12]` GAIN_MODE_M and `ISIF_2DLSCCFG[10:8]` GAIN_MODE_N bit fields. The possible values are 8, 16, 32, 64, and 128. Smaller values lead to higher memory bandwidth requirements. Hence, the worst case is achieved by setting an 8 × 8 paxel size.

When LSC is enabled it automatically prefetches two lines of gain values and two lines of offset values (if this is enabled). When the first VD comes, it again requests one line of gain values and one line of offset values (if this is enabled). Then, it again fetches one line of gain values and one line of offset values (if this is enabled) after `ISIF_2DLSCCFG[10:8]` GAIN_MODE_N lines. It continues to do so until the last row of paxels. For the last row of paxels, it fetch two lines of gain values and two lines of offset values (if this is enabled), which are used for the following frame.

By default, LSC creates peak bandwidth requirements. To avoid this, the MTC bandwidth limiter must be used to space the request over time.

The MTC bandwidth limiter must be used to smooth the bandwidth requirements of the LSC module. The MTC bandwidth limiter can be set with the `ISP5_BL_MTC_1.ISIF_R` register.

The principle is that instead of reading the gain and offset data as fast as possible, use the time that it takes for `ISIF_2DLSCCFG[10:8]` GAIN_MODE_N lines to pass through the ISP to read the data.

[Table 9-249](#) gives the estimated delay between 32-byte MTC requests for different pixel clock frequencies and assumes the L3_MAIN clock at 212.8 MHz.

Table 9-249. ISS ISP ISIF Read Port Bandwidth

Pixel Clock	Max Bandwidth MB/s	Expected Delay Between MTC Requests
212.8	25.07	255 cycles = 1275 ns
100	12.5	510 cycles = 2550 ns
10	1.25	5103 cycles = 2515 ns

When the bandwidth limiter is used, ensure that there is enough time for the data prefetching.

- LSC must be enabled at least $2 \times \text{ISIF_2DLSCCFG}[10:8]$ GAIN_MODE_N lines before the first VD.
- There must be at least $\text{ISIF_2DLSCCFG}[10:8]$ GAIN_MODE_N lines of blanking. If there is not enough blanking, multiply the bandwidth requirement by 2 (that is, ensure two lines of gain and offset data can be fetched within the time of $\text{ISIF_2DLSCCFG}[10:8]$ GAIN_MODE_N lines.

9.3.3.9.20 ISS ISP ISIF Events and Status Checking

The ISIF module can generate four different interrupts: VDINT0, VDINT1, VDINT2, and 2DLSCINT. The $\text{ISIF_SYNCEN}[0]$ SYEN bit must be enabled to receive any of the ISIF interrupts.

9.3.3.9.20.1 ISS ISP ISIF VDINT0, VDINT1, and VDINT2 Interrupts

As shown in [Figure 9-169](#), the VDINT0, VDINT1, and VDINT2 interrupts occur relative to the VD pulse. The trigger timing is selected by using the $\text{ISIF_MODESET}[2]$ VDPOL bit setting. VDINT0, VDINT1, and VDINT2 occur after receiving the number of horizontal lines (HD pulse signals) set in the $\text{ISIF_VDINT0}[14:0]$ CDV0, $\text{ISIF_VDINT1}[14:0]$ CDV1, and $\text{ISIF_VDINT2}[14:0]$ CDV2 register fields, respectively.

NOTE: In the case of BT.656 input mode, there is a VD at the beginning of each field. Therefore, there are two interrupts for each frame (that is, one for each field).

If the $\text{ISIF_MODESET}[2]$ VDPOL bit is set to 0, the VDINT0, VDINT1, and VDINT2 HD counters begin counting HD pulses from the rising edge of the external VD.

Figure 9-169. ISS ISP ISIF VDINT0/VDINT1/VDINT2 Interrupt Behavior When VDPOL = 0

camss-611

If the $\text{ISIF_MODESET}[2]$ VDPOL bit is set to 1, the VDINT0, VDINT1, and VDINT2 HD counters begin counting HD pulses from the falling edge of the external VD.

Figure 9-170. ISS ISP ISIF VDINT0/VDINT1/VDINT2 Interrupt Behavior When VDPOL = 1

camss-612

9.3.3.9.20.2 ISS ISP ISIF 2DLSCINT Interrupt

For more information, see [Section 9.3.3.9.10.1.5, ISS ISP ISIF 2D-LSC Events and Status Checking](#).

9.3.3.9.20.3 ISS ISP ISIF Status Checking

The [ISIF_MODESET](#)[15] MDFS bit is set when the field status is on an even field, and it is cleared when the field status is on an odd field.

The 2D-LSC has a register that monitors the status of the LSC. For more information, see [Section 9.3.3.9.10.1.5](#), ISS ISP ISIF 2D-LSC Events and Status Checking.

9.3.3.10 ISS ISP BL Functional Description

9.3.3.10.1 ISS ISP BL Overview

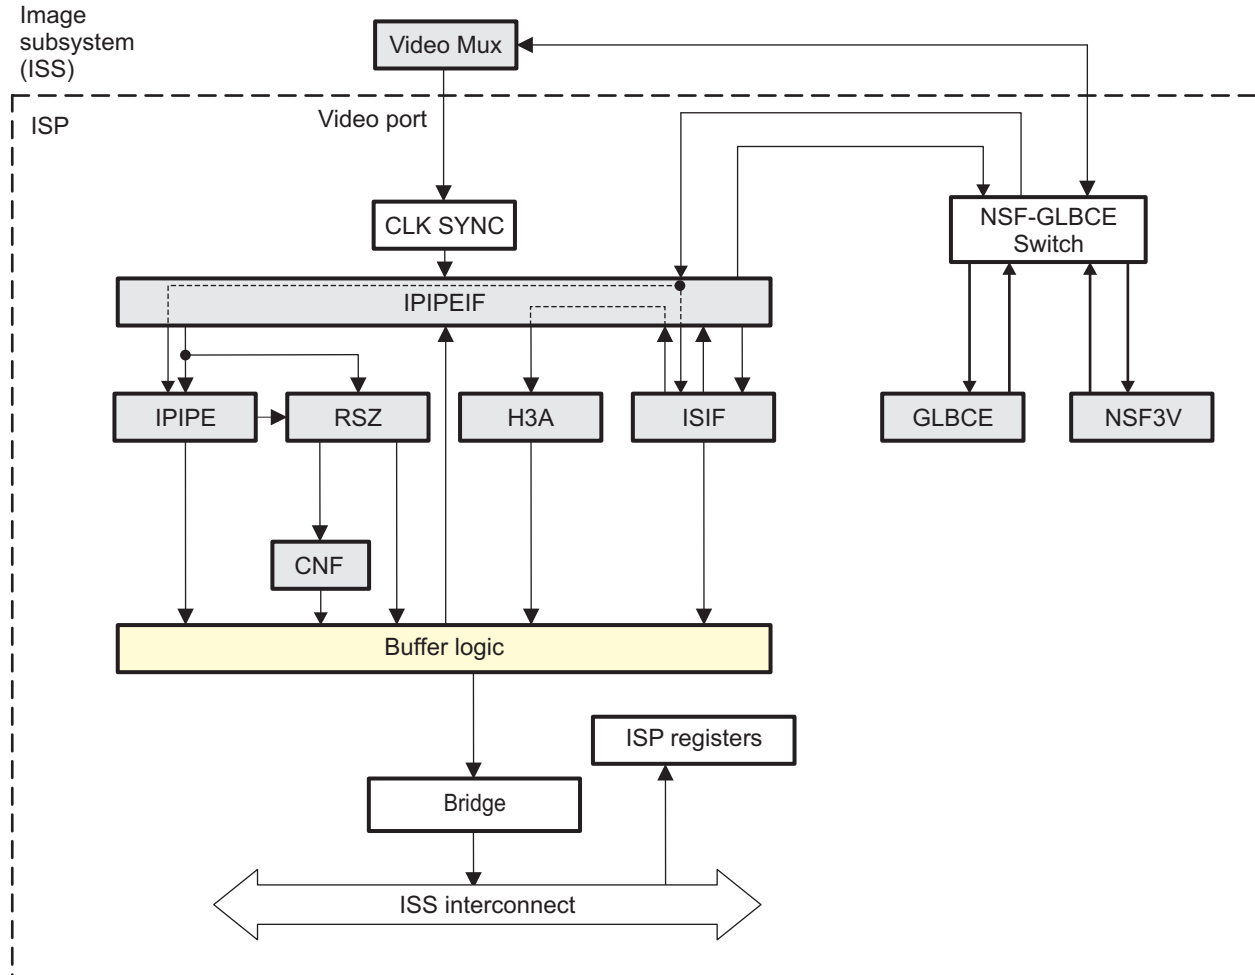

The BL module arbitrates and merges the memory requests of the ISP master module. The BL module also generates interrupts upon frame completion for the following modules. The interrupt generation is delayed until the transfer completes (acknowledge signal is returned). The following interrupts are delayed by the BL module:

- RSZ module resizer RSZ-A EOF
- RSZ module resizer RSZ-B EOF
- H3A module EOF
- IPIPE module EOF

The BL uses two different types of interfaces:

- MTC protocol is used between the ISP modules and the BL.
- VBUSM is use on the BL master port interface.

[Figure 9-171](#) show the BL module connections to other submodules of the ISP.

Figure 9-171. ISS ISP BL High-Level Diagram

camisp-003f

9.3.3.10.2 ISS ISP BL Functional Description

The BL merges the memory requests of the ISP master module to memory (read/write). The BL interfaces with all the ISP modules through a 32-bit-wide bus.

The ISP modules make memory requests of 32 bytes. Additional signals, SOF for read and EOF for write, are included to deal with boundary conditions in frame transitions.

The BL arbitration is divided into two parts: a bus hog and a fixed priority arbitration. Bus hog refers to the property of the buffer logic that gives higher priority to the module that last sent or received data. RSZ module MTC write port 0 and RSZ module MTC write port 1 are excluded from the bus hog.

The buffer logic is to be programmed to maximize the memory bandwidth: it makes maximum burst requests of 128 bytes (8×128 bits) for reads and writes. The BL can generate burst sizes of 2×128 , 4×128 , 6×128 , and 8×128 bits.

NOTE: The ISP interface supports burst sizes of only 1, 2, 4, and 8×128 bits. If the BL generates a 6×128 -bit request, it is divided into a 4×128 -bit request, followed by a 2×128 -bit request.

To use the memory bandwidth efficiently, the BL interfaces with the memory through a high-bandwidth bus (128 bits wide).

The BL handles memory requests for the following modules:

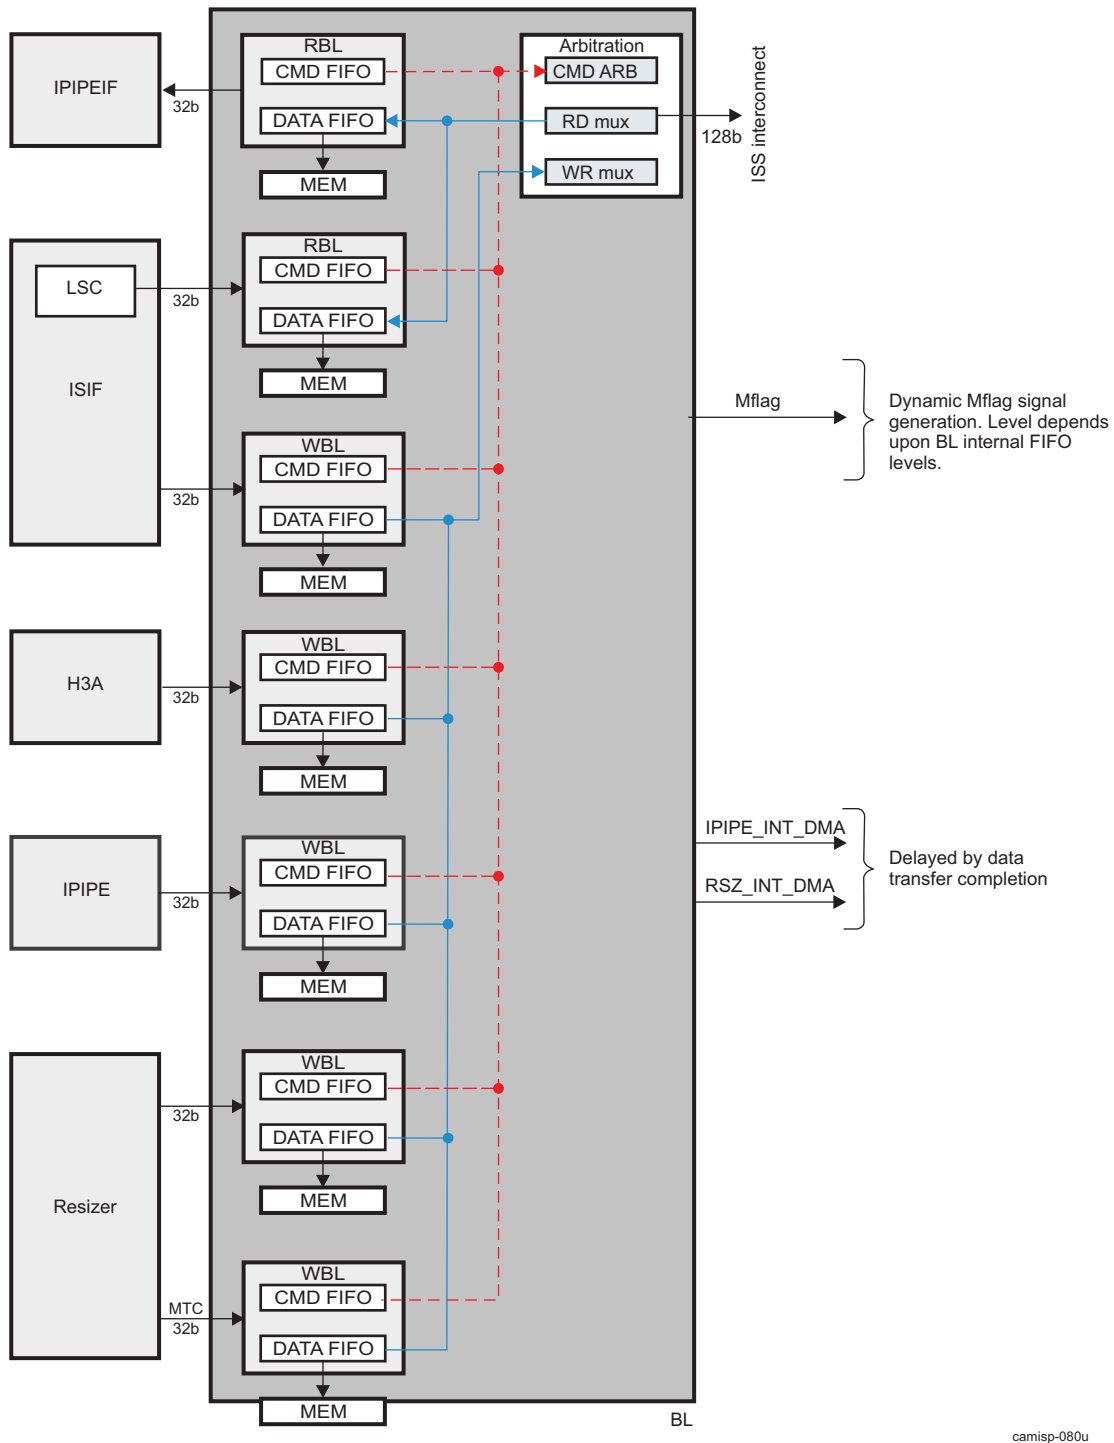

- IPIPEIF module read port
- ISIF-LSC module read port
- ISIF module write port
- H3A module write port
- RSZ module write port 0
- RSZ module write port 1

From a use case point of view, the following sharing and priority arrangement is used. All reads have higher priority than writes; for reads: IPIPEIF > ISIF-LSC, and for writes: ISIF > IPIPE > RSZ 0 > RSZ 1 > H3A.

NOTE: The BL can generate a static or a dynamic MFlag signal. The MFlag signal is used by the ISS arbitration to consider the urgency of the requests coming from the ISP. The dynamic MFlag feature is enabled from the [ISP5_CTRL\[21\]](#) MFLAG bit.

[Figure 9-172](#) shows the BL top-level block diagram. The figure highlights the two clock domains that are used.

Figure 9-172. ISS ISP BL Block Diagram

NOTE: The BL module has no registers. The configurations come from the top level of the ISP. See [Section 9.3.4, ISS ISP Register Manual](#), for register details.

9.3.3.10.3 ISS ISP BL Address Alignment

The BL module ensures maximum memory efficiency by realigning data to a 128-byte address boundary. In all cases, the BL accesses are 32-byte-aligned: address [4:0] is always 0.

This is required when the input address is a multiple of 32 bytes, not 128 bytes. The BL issues a nonaligned burst until it reaches a 128-byte boundary, and then keeps making a 128-byte request until the end of the line. Eventually, although the last burst in a line may not be a multiple of 128 bytes, it will always be a multiple of 32 bytes, as shown in [Figure 9-173](#).

Figure 9-173. ISS ISP BL Address Alignment

camss-687

9.3.3.10.4 ISS ISP BL Out-of-Order Responses

BL supports out-of-order responses. The out-of-order response is handled by having up to 16 outstanding CIDs (reads and writes).

If any of the CIDs are not outstanding, a command is accepted from the highest prioritized buffer with a request. The CID availability is cleared when status complete is received. The outstanding commands can be all reads or all writes or any combination. The CID that is allocated is the lowest number of the 16 that are available when the command is accepted. As soon as a CID is released it is used if a command is available.

The VBUSM2OCP module transforms the VBUMS CIDs into OCP MFlag signals. There can be only one outstanding CID per tag. It is not authorized to make a new request on a tag which is already waiting for a response.

9.3.3.10.5 ISS ISP BL Stalling

The BL can stall the requests from the initiator modules for reads and writes

9.3.3.10.5.1 ISS ISP BL Stalling Write Requests

One reason for the BL to stall write requests is that because back pressure usually exists on the system memory and requests cannot be issued as fast as required. In that case the BL must stall requests from the initiator modules. The BL module cannot know whether stalling the request will lead to an initiator overflow or not. The RSZ module can support back pressure from the BL module when it is configured in bypass mode. The input buffer memory can be used to store data from the IPIPE and IPIPEIF modules. If the RSZ input buffer overflows, an interrupt is issued.

9.3.3.10.5.2 ISS ISP BL Stalling Read Requests

The BL may also stall read requests from the ISIF-LSC and IPIPEIF modules. When data comes from an image sensor, there is no way to stop the sensor. If the read request is stalled too long, the LSC module may eventually underflow. When the IPIPEIF reads all its data from memory, the IPIPEIF stalls transfers to successive modules by masking the clock.

9.3.3.10.6 ISS ISP BL Dynamic and Static MFlag Generation

NOTE: The following applies when `ISP5_CTRL[21] MFLAG = 1`. The MFlag value is static.

The BL outputs `cpriority[2:0]` and `cepriority[2:0]` signals on its VBUS master port interface. On the VBUSM side, these signals are aligned with the request (`creq`). Both values actually repeat register input signals. The lower value (0) corresponds to the higher priority.

The MFlag signal does not need to be aligned with the request. The signal can change value anytime.

In the ISP VBUSM2 interface bridge, the `cepriority` signal is ignored and only the `cpriority` signal is used. Because the priority value is set up by a register setting, the value is not dynamically modified. [Table 9-250](#) shows how the `cpriority` values are mapped to the interface MFlag signal, which is present on the ISP master interface and set in the `ISP5_CTRL[3:1] VBUSM_CPRIORITY` bit field.

Table 9-250. ISS ISP BL `cpriority` to MFlag With `ISP5_CTRL[21] MFLAG = 1`

MFlag[1:0]	Description
00	Normal priority <code>cpriority[2:0] = 4, 5, 6, 7</code>
01	Medium priority <code>cpriority[2:0] = 2, 3</code>
10	Reserved
11	High priority <code>cpriority[2:0] = 0, 1</code>

NOTE: The following applies when the `ISP5_CTRL[21] MFLAG = 0`. The MFlag value is dynamic.

This feature is enabled at reset. The purpose for dynamic MFlag generation is to monitor the FIFO levels. Thresholds are used to increase or decrease the MFlag values. There are different implementations for read and write requestors.

An individual MFlag value is generated for each FIFO and then ORed altogether and exported at the BL boundary. The MFlag signal generation does not affect the BL arbitration scheme.

- Writes: To prevent overflows in the BL, dynamic MFlag signal generation gives higher priority to FIFOs that are almost full:
 - Low FIFO level = 50 percent
 - High FIFO level = 75 percent
 - FIFOs with more than 75 percent fill level have high priority: MFlag = 11
 - FIFOs between 50 and 75 percent fill level have medium priority: MFlag = 01
 - FIFOs below 50 percent fill level have low priority: MFlag = 00

[Table 9-251](#) gives the low- and high-level priority thresholds for write initiators.

Table 9-251. ISS ISP BL MFlag Write Low- and High-Level Priority Thresholds

	ISIF	H3A	IPIPE	RSZ
Access type	Write	Write	Write	Write
Buffer size	64 x 128	64 x 128	48 x 128	64 x 136
50% low level	32 x 128	32 x 128	24 x 128	32 x 136
75% high level	48 x 128	48 x 128	36 x 128	48 x 128

- Reads: The dynamic MFlag signal generation depends on the reserved data units in the initiator data FIFO. The reserved data units correspond to read commands waiting to be sent on the interface bus, plus the read commands that have been sent on the interface bus and for which data responses have not yet arrived.
- The total FIFO size in bytes can be expressed as reserved data units (bytes) + data bytes stored (bytes) + empty space (bytes). By definition, empty space is lower than a burst size (128 bytes).
 - Low FIFO level = 25 percent

- High FIFO level = 50 percent
- Data bytes stored + empty space (bytes) = 50 percent of FIFO size: MFlag = 00
- Data bytes stored + empty space (bytes) = 50 percent of FIFO size: MFlag = 01
- Data bytes stored + empty space (bytes) = 25 percent of FIFO size: MFlag = 11

Table 9-252 gives the low- and high-level priority thresholds for read initiators

Table 9-252. ISS ISP BL MFlag Read Low- and High-Level Priority Thresholds

	IPIPEIF	ISIF-LSC
Access type	Read	Read
Buffer size	64 × 128	32 × 128
25% buffer size	16 × 128	8 × 128
50% buffer size	32 × 128	16 × 128

9.3.3.10.7 ISS ISP BL VBUSM2OCP Last Beat Command Delay

The VBUSM2OCP module bridge implements the following function to work around a limitation of the BL module, which does not send back-to-back requests to the ISS, thereby leading to possible situations where the ISP loses arbitration at the ISS level.

To fully benefit from dynamic MFlag generation (see [Section 9.3.3.10.6, ISS ISP BL Dynamic and Static MFlag Generation](#)), the following function is present in the VBUSM2OCP module bridge:

- The delay occurs only if BL MFlag = `ISP5_BL_VBUSM[5] MFLAG_THRES`.
- The MFlag value used is whatever is available when the last beat comes on the interface bus.
- The last beat of the interface request (read or write) is held until one cycle before a new command (read or write). This is achieved by masking the last beat of the interface command at the ISP interface.

The last beat is unmasked on the first event of one cycle before a new interface command, or the delay counter that uses the value counter of the `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` bit field expires (has decremented to 0). The `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` bit field must be set before the request on the BL starts. If the value of the `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` bit field is changed during the pending requests, the delay counter is not updated.

9.3.3.10.8 ISS ISP BL Peak Memory Bandwidth Reduction

To limit the peak memory bandwidth generated by the IPIPEIF (read port), ISIF (read port), and H3A (write port) modules, a bandwidth limiter is placed between the modules and the BL. The RSZ module has this function built in and therefore does not need a bandwidth limiter.

The bandwidth limiter enables control of the minimum interval between two consecutive memory requests.

This function is controlled by the `ISP5_BL_MTC_1` and `ISP5_BL_MTC_2` registers. When the registers are set to 0, the function is not modified (that is, the bandwidth limiter is disabled). For the RSZ module, it is controlled by the `RSZ_DMA_RZA` and `RSZ_DMA_RZB` registers.

9.3.3.11 ISS ISP Memory Mapping

A total of 64 KiB is reserved for the ISP registers and memories. [Table 9-253](#) describes the memory map.

Table 9-253. ISS ISP Memory Mapping

Mem Map	Start	End	Size	Comments
ISP6 SYS_1	0x4224 0000	0x4224 009F	160	ISP configuration registers (set #1)

Table 9-262. ISP5_SYSCONFIG

Address Offset	0x0000 0010	Instance	ISP6P5_SYS1
Physical Address	0x4224 0010		
Description	Clock management configuration		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																STANDBYMODE		RESERVED		SOFTRESET		AUTO_IDLE									

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x0
5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 0x3: Reserved 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator. IP module shall not generate (initiator-related) wakeup events. Generation of the MStandby signal shall be initiated by the firmware by writing <code>ISP5_CTRL.MSTANDBY = 1</code> .	RW	0x2
3:2	RESERVED		R	0x0
1	SOFTRESET	Software reset. The soft reset will cause the MStandby to be asserted as the reset value of the <code>ISP5_CTRL.MSTANDBY</code> bit is 1. After a soft reset, the software shall ensure not to perform any access for 16 clock cycles (OCP-slave port frequency) after writing this bit. The OCP slave port is running at half the frequency of the functional clock. Before issuing a soft reset, the software shall ensure that no more traffic is being generated by the ISP5. Basically, it means that either the camera module shall be stopped from sending data and/or that the ISP5 modules are disabled. The last interrupt triggered by the ISP5 design upon completion of the frame processing is <code>rsz_int_dma</code> . This <code>rsz_int_dma</code> event shall be used to enable clean termination of the processing. The software shall wait a few hundred cycles to trigger the soft reset after upon assertion of the <code>rsz_int_dma</code> , this is to ensure that the BL is completely drained. Furthermore the software shall set the ISP5 in standbymode before issuing the soft reset: Set <code>ISP5_SYSCONFIG.STANDBYMODE = 2</code> (smart standby) Set <code>ISP5_CTRL.MSTANDBY</code> to 1 Poll for <code>ISP5_CTRL.MSTANDBY_WAIT = 1</code> . Then, the soft reset can be applied <code>ISP5_SYSCONFIG.SOFTRESET = 1</code> . 0x0: Reset done, no pending action 0x1: Reset (software or other) ongoing	RW	0x0
0	AUTO_IDLE	Auto clock gating. Always enabled.	R	0x1

26	RESERVED		R	0x0
25	IPIPE_INT_EOF	0x0: No action 0x1: Set event (debug)	RW	0x0
24	H3A_INT_EOF	0x0: No action 0x1: Set event (debug)	RW	0x0
23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the eof signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. 0x0: No action 0x1: Set event (debug)	RW	0x0
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the eof signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. 0x0: No action 0x1: Set event (debug)	RW	0x0
21:20	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
19	RSZ_FIFO_IN_BLK_ERR	<p>This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the <code>rsz_int_reg</code> event of frame N is triggered before the <code>rsz_int_dma</code> of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware shall take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>0x0: No action 0x1: Set event (debug)</p>	RW	0x0
18	RSZ_FIFO_OVF	<p>Resizer module overflow This event is set when overflow happens in the RESIZER module. This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware shall take care to use a lower pixel clock at the input of the resizer module. Depending on the mode being used, the overflow can happen at different places: 1. Bypass mode: overflow happened in the input circular buffer. 2. Pass through mode: overflow happened on the module output interface (MTC) 3. Normal resize mode: overflow happened in the input circular buffer. This event signals that overflow happened in the input data buffering submodule. 1. In normal resizer mode or bypass mode, this event will be triggered when the This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware shall take care to use a lower pixel clock at the input of the resizer module. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>0x0: No action 0x1: Set event (debug)</p>	RW	0x0
17	RSZ_INT_CYC_RZB	<p>RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that <code>RSZ_IRQ_RZB</code> output lines have been written out to the <code>RZB_SDR_Y</code> buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the <code>RZB_SDR_Y_PTR_E</code> register) is a multiple of <code>RSZ_IRQ_RZB</code>. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>0x0: No action 0x1: Set event (debug)</p>	RW	0x0
16	RSZ_INT_CYC_RZA	<p>RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that <code>RSZ_IRQ_RZA</code> output lines have been written out to the <code>RZA_SDR_Y</code> buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the <code>RZA_SDR_Y_PTR_E</code> register) should be a multiple of <code>RSZ_IRQ_RZA</code>. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>0x0: No action 0x1: Set event (debug)</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
15	RSZ_INT_DMA	This event is triggered when the last eof (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. <code>rsz_int_dma</code> is a true indication that all processing is finished for the particular frame on both resizer engines. 0x0: No action 0x1: Set event (debug)	RW	0x0
14	RSZ_INT_LAST_PIX	This event is triggered when the last pixel of the valid area is received. 0x0: No action 0x1: Set event (debug)	RW	0x0
13	RSZ_INT_REG	This event is triggered when the first pixel of the valid area is received. Shadowed registers can be updated at any time but the new value will take effect on the next <code>rsz_int_reg</code> event. 0x0: No action 0x1: Set event (debug)	RW	0x0

Table 9-268. ISP5_IRQSTATUS

Address Offset	0x0000 0028	Instance	ISP6P5_SYS1
Physical Address	0x4224 0028		
Description	Per-event 'enabled' interrupt status vector. Enabled status isn't set unless event is enabled. Write 1 to clear the status after interrupt has been serviced (raw status gets cleared, i.e. even if not enabled). The ISP5 outputs 4 interrupt lines ISP5_IRQ0 to ISP5_IRQ3. Any internal ISP5 event can be merged on the 4 lines. A same event shall be enabled on only one interrupt line. There is another interrupt register in the memory map, look for ISP5_IRQSTATUS2		
Type	RW

24	H3A_INT_EOF	0x0: No action 0x1: Clear (raw) event	RW	0x0
23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the eof signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. 0x0: No action 0x1: Clear (raw) event	RW	0x0

Bits	Field Name	Description	Type	Reset
22	RSZ_INT_EOF0	<p>RESIZER module event: This event signals that the BL has received the eof signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory.</p> <p>0x0: No action</p> <p>0x1: Clear (raw) event</p>	RW	0x0
21:20	RESERVED		R	0x0
19	RSZ_FIFO_IN_BLK_ERR	<p>This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware shall take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>0x0: No action</p> <p>0x1: Clear (raw) event</p>	RW	0x0
18	RSZ_FIFO_OVF	<p>This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware shall take care to use a lower pixel clock at the input of the resizer module. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>0x0: No action</p> <p>0x1: Clear (raw) event</p>	RW	0x0
17	RSZ_INT_CYC_RZB	<p>RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>0x0: No action</p> <p>0x1: Clear (raw) event</p>	RW	0x0
16	RSZ_INT_CYC_RZA	<p>RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that RSZ_IRQ_RZA output lines have been written out to the RZA_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the RZA_SDR_Y_PTR_E register) should be a multiple of RSZ_IRQ_RZA. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>0x0: No action</p> <p>0x1: Clear (raw) event</p>	RW	0x0
15	RSZ_INT_DMA	<p>This event is triggered when the last eof (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. rsz_int_dma is a true indication that all processing is finished for the particular frame on both resizer engines.</p> <p>0x0: No action</p> <p>0x1: Clear (raw) event</p>	RW	0x0

Address Offset	0x0000 0034	Instance	ISP6P5_SYS1
Physical Address	0x4224 0034		
Description	Per-event raw interrupt status vector. Raw status is set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug. The ISP5 outputs 4 interrupt lines ISP5_IRQ0 to ISP5_IRQ3. Any internal ISP5 event can be merged on the 4 lines. A same event shall be enabled on only one interrupt line. There is another interrupt register in the memory map, look for ISP5_IRQSTATUS_RAW2

24	H3A_INT_EOF	0x0: No action 0x1: Set event (debug)	RW	0x0
23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the eof signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. 0x0: No action 0x1: Set event (debug)	RW	0x0
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the eof signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. 0x0: No action 0x1: Set event (debug)	RW	0x0
21:20	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
19	RSZ_FIFO_IN_BLK_ERR	<p>This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the <code>rsz_int_reg</code> event of frame N is triggered before the <code>rsz_int_dma</code> of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware shall take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>0x0: No action 0x1: Set event (debug)</p>	RW	0x0
18	RSZ_FIFO_OVF	<p>Resizer module overflow This event is set when overflow happens in the RESIZER module. This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware shall take care to use a lower pixel clock at the input of the resizer module. Depending on the mode being used, the overflow can happen at different places: 1. Bypass mode: overflow happened in the input circular buffer. 2. Pass through mode: overflow happened on the module output interface (MTC) 3. Normal resize mode: overflow happened in the input circular buffer. This event signals that overflow happened in the input data buffering submodule. 1. In normal resizer mode or bypass mode, this event will be triggered when the This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware shall take care to use a lower pixel clock at the input of the resizer module. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>0x0: No action 0x1: Set event (debug)</p>	RW	0x0
17	RSZ_INT_CYC_RZB	<p>RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that <code>RSZ_IRQ_RZB</code> output lines have been written out to the <code>RZB_SDR_Y</code> buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the <code>RZB_SDR_Y_PTR_E</code> register) is a multiple of <code>RSZ_IRQ_RZB</code>. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>0x0: No action 0x1: Set event (debug)</p>	RW	0x0
16	RSZ_INT_CYC_RZA	<p>RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that <code>RSZ_IRQ_RZA</code> output lines have been written out to the <code>RZA_SDR_Y</code> buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the <code>RZA_SDR_Y_PTR_E</code> register) should be a multiple of <code>RSZ_IRQ_RZA</code>. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>0x0: No action 0x1: Set event (debug)</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
15	RSZ_INT_DMA	This event is triggered when the last eof (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. <code>rsz_int_dma</code> is a true indication that all processing is finished for the particular frame on both resizer engines. 0x0: No action 0x1: Set event (debug)	RW	0x0
14	RSZ_INT_LAST_PIX	This event is triggered when the last pixel of the valid area is received. 0x0: No action 0x1: Set event (debug)	RW	0x0
13	RSZ_INT_REG	This event is triggered when the first pixel of the valid area is received. Shadowed registers can be updated at any time but the new value will take effect on the next <code>rsz_int_reg</code> event. 0x0: No action 0x1: Set event (debug)	RW	0x0

Table 9-294. ISP5_IRQENABLE_SET_3

Address Offset	0x0000 005C	Instance	ISP6P5_SYS1
Physical Address	0x4224 005C		
Description	Per-event interrupt enable bit vector. Write 1 to set (enable interrupt). Readout equal to corresponding _CLR register. The ISP5 outputs 4 interrupt lines ISP5_IRQ0 to ISP5_IRQ3. Any internal ISP5 event can be merged on the 4 lines. A same event shall be enabled on only one interrupt line. There is another interrupt register in the memory map, look for ISP5_IRQENABLE_SET2 .

24	H3A_INT_EOF	0x0: No action 0x1: Enable interrupt	RW	0x0
23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the eof signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. 0x0: No action 0x1: Enable interrupt	RW	0x0
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the eof signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. 0x0: No action 0x1: Enable interrupt	RW	0x0
21:20	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
19	RSZ_FIFO_IN_BLK_ERR	<p>This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the <code>rsz_int_reg</code> event of frame N is triggered before the <code>rsz_int_dma</code> of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware shall take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>0x0: No action 0x1: Enable interrupt</p>	RW	0x0
18	RSZ_FIFO_OVF	<p>This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware shall take care to use a lower pixel clock at the input of the resizer module. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>0x0: No action 0x1: Enable interrupt</p>	RW	0x0
17	RSZ_INT_CYC_RZB	<p>RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that <code>RSZ_IRQ_RZB</code> output lines have been written out to the <code>RZB_SDR_Y</code> buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the <code>RZB_SDR_Y_PTR_E</code> register) is a multiple of <code>RSZ_IRQ_RZB</code>. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>0x0: No action 0x1: Enable interrupt</p>	RW	0x0
16	RSZ_INT_CYC_RZA	<p>RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that <code>RSZ_IRQ_RZA</code> output lines have been written out to the <code>RZA_SDR_Y</code> buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the <code>RZA_SDR_Y_PTR_E</code> register) should be a multiple of <code>RSZ_IRQ_RZA</code>. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>0x0: No action 0x1: Enable interrupt</p>	RW	0x0
15	RSZ_INT_DMA	<p>This event is triggered when the last eof (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. <code>rsz_int_dma</code> is a true indication that all processing is finished for the particular frame on both resizer engines.</p> <p>0x0: No action 0x1: Enable interrupt</p>	RW	0x0

24	MSTANDBY	<p>MStandby signal assertion and de-assertion control for power management transitions. After software reset, this bit is asserted. Write '1' to transition from normal mode to idle mode. The firmware needs to ensure that no more ISP5 processing is ongoing before setting up this bit. Write '0' to transition from idle mode to normal mode. The software should poll ISP5_CTRL.MSTANDBY_WAIT = 0 after writing ISP5_CTRL.MSTANDBY = 0 in a transition from idle to normal mode.</p> <p>0x0: De-assert MStandby signal. May not be immediate due to power management handshaking btw the MStandby and Wait signals.</p> <p>0x1: Assert MStandby signal</p>	RW	0x1
23	VD_PULSE_EXT	<p>VD pulse extension enable This bit enables or disables the VD extension bridge. By default, the bridge is enabled. At ISS level, it is expected that IPS5_CTRL.VD_PULSE_EXT = 1 when the VPORT gets data from the CSI2 RX module and IPS5_CTRL.VD_PULSE_EXT = 0 when the VPORT gets data from the parallel interface or the CCP2 RX module. There shall be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes.</p> <p>0x0: Disabled</p> <p>0x1: Enabled</p>	RW	0x1
22	PCLK_INV	<p>Pixel clock inversion This bit enables or disables pixel clock inversion. The ISP5 always samples the data on the rising edge of the pixel clock. Enabling the inversion shifts the resampling period by 1/2 a pixel clock period. PCLK needs to be disabled at ISS level before setting this bit.</p> <p>0x0: Normal</p> <p>0x1: Inversed</p>	RW	0x0
21	MFLAG	<p>MFlag signal generation control This bit controls how the OCP MFlag signal is generated on the ISS NOC.</p> <p>0x0: The MFlag value is dynamic.</p> <p>0x1: The MFlag value is static. The value is set with the ISP5_CTRL.VBUSM_CPRIORITY bitfield.</p>	RW	0x0
20	MSTANDBY_WAIT	<p>MStandby / Wait power management status bit. The power management framework of the ISP5 is based on the handshaking of the MStandby and Wait signals. The software is not supposed to write inside the ISP5 slave port and initiate traffic when ISP5_CTRL.MSTANDBY bit is written. The software can poll this bit to know when MStandby signal is deasserted.</p> <p>0x0: MStandby signal is de-asserted</p> <p>0x1: MStandby signal is asserted</p>	R	0x0
19	GLBCE_CLK_ENABLE	<p>GLBCE clock enable</p> <p>0x0: Disable</p> <p>0x1: Enable</p>	RW	0x0
18	NSF3V_CLK_ENABLE	<p>NSF3V clock enable</p> <p>0x0: Disable</p> <p>0x1: Enable</p>	RW	0x0
17	CNFB_CLK_ENABLE	<p>CNFB clock enable</p> <p>0x0: Disable. Since CNF-B is removed , it doesn't have any effect</p> <p>0x1: Enable. Since CNF-B is removed , it doesn't have any effect.</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
16	CNFA_CLK_ENABLE	CNFA clock enable 0x0: Disable 0x1: Enable	RW	0x0
15	BL_CLK_ENABLE	BL clock enable 0x0: Disable 0x1: Enable	RW	0x0
14	ISIF_CLK_ENABLE	ISIF clock enable The ISP5 will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. There shall be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes. 0x0: Disable 0x1: Enable	RW	0x0
13	H3A_CLK_ENABLE	H3A clock enable The ISP5 will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable	RW	0x0
12	RSZ_CLK_ENABLE	RESIZER clock enable The ISP5 will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable	RW	0x0
11	IPIPE_CLK_ENABLE	IPIPE clock enable The ISP5 will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. If DPC is working before NSF3V (working as pre-NSF3V DPC), this bit must be asserted for SW to access DPC MMR entries. 0x0: Disable 0x1: Enable	RW	0x0
10	IPIPEIF_CLK_ENABLE	IPIPEIF clock enable The ISP5 will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable	RW	0x0
9	SYNC_ENABLE	PCLK Sync module enable 0x0: Disable. Shall only be used when the video port is not receiving data, e.g., data is read from the IPIPEIF module memory read port. 0x1: Enable. Shall be used when the video port is receiving data.	RW	0x0
8	PSYNC_CLK_SEL	PCLK Sync clock select. This bit selects the clock which is used to resynchronize the input pixel clock. 0x0: Use ISP6_CFG_CLK. Can be used if the input pixel clock is always lower than 213 MHz. Also, this option must not be chosen if DPC is used with CAL if (CAL - DPC - NSF3V - CAL case.) 0x1: ISP6_FUNC_CLK. Shall be used if the pixel clock is higher than 213 MHz or DPC is used with CAL port. (CAL - DPC - NSF3V - CAL)	RW	0x0
7:4	VBUSM_CIDS	BL MAX VBUSM CIDs The BL module supports up to 16 CIDs/tags. This bitfield setups the maximum number of CIDs/tags that the BL can use. The actual number of CIDs/tags is setup by VBUSM_CIDS + 1. Tag number 0 to VBUSM_CIDS are used.	RW	0xf

Bits	Field Name	Description	Type	Reset
3:1	VBUSM_CPRIORITY	BL VBUSM priority setting 0x6: Normal Priority VBUSM cpriority[2:0] = 6 0x1: High Priority VBUSM cpriority[2:0] = 1 0x7: Normal Priority VBUSM cpriority[2:0] = 7 0x0: High Priority VBUSM cpriority[2:0] = 0 0x2: Medium Priority VBUSM cpriority[2:0] = 2 0x4: Normal Priority VBUSM cpriority[2:0] = 4 0x5: Normal Priority VBUSM cpriority[2:0] = 5 0x3: Medium Priority VBUSM cpriority[2:0] = 3	RW	0x4
0	OCP_WRNP	ISP5 OCP master port non-posted write control. 0x0: All writes are non posted. 0x1: All writes are posted.	RW	0x0

Table 9-310. ISP5_MPSR

Address Offset	0x0000 007C	Instance	ISP6P5_SYS1
Physical Address	0x4224 007C		
Description	ISP5 memory access register. One need to pay attention when setting the bit fields in this register such that there is no conflict between the cpu and module accesses. Usually, the ISP5 modules shall have access to the memories and it's only when the isp5 is idle (vertical blanking period or module disabled that the cpu can access the memories. CPU has memory access If the cpu has memory access (read or write) and CPU has priority, it will cause data corruption if the module tries to perform concurrent memory accesses. The module cannot know that the read or write access has not taken place because of cpu accesses.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Address Offset	0x0000 0088	Instance	ISP6P5_SYS1
Physical Address	0x4224 0088		
Description	BL VBUSM TUNING REGISTER The settings in the register are static and not expected to be modified dynamically.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MFLAG_THRES		LASTCMD_DLY													

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x0
5	MFLAG_THRES	MFLAG Threshold value The value of this bit field is a threshold which is compared to the MFlag output of the ISP5. If the BL MFlag signal is greater or equal to this threshold the last beat of the VBUSM command is delayed by LASTCMD_DLY cycles. Only values 0, 1 are valid, the least significant bit is tied off to 1 to make a 2-bit bitfield. 0x0: Thres = 1 0x1: Thres = 3	RW	0x1
4:0	LASTCMD_DLY	The value of this bitfield represents a delay expressed in cycles (L3 clock). This value is used to delay the last beat of the VBUSM command such that the ISP5 does not lose arbitration at the NOC level because the BL does not generate back to back requests by default. The last beat is delayed until the counter expires or the new request is accepted. This delay is used when the MFlag output of the ISP5 is greater or equal to MFLAG_THRES. One can set this value to 0 to disable the last command beat delay.	RW	0x4

RESERVED																RSZ_FRACDIV															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RSZ_FRACDIV	Fractional clock divider value. The fractional clock divider gates the read requests made to the input data buffer such that the input data buffer is read at an average frequency equal to FFCLK instead of FCLK. The value of FFCLK depends upon the upscaling ratios as well as the input pixel clock. We have $FFCLK = FCLK / FRACDIV$ MHz and $RSZ_FRACDIV = 65536 / FRACDIV$. When $RSZ_FRACDIV = 65536$, we have: $FFCLK = FCLK$.	RW	0xffff

1	WRT	Video port WEN signal selection This bit selects whether the WEN signal which is present on the IPIPE and IPIPEIF video port is used or not to select the input data. If WRT is 0, the RESIZER module ignores the WEN signal and processes all image frame while RESIZER is enabled. If WRT is 1, the RESIZER module only processes the lines that arrived while the WEN is high. HD is used to sample the WEN signal. 0x0: Disable 0x1: Enable	RW	0x0
0	OST	The processing mode selection of the RESIZER module. Value 0 indicates the mode of "free run", value 1 indicates the mode of "one shot". 0x0: Free running 0x1: One shot	RW	0x0

RESERVED																HPS															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	HPS	Horizontal Start Position The RSZ_SRC_HPS register has two functions. The first function is to compensate for possible delay btw the HD pulse and the first valid data, it is possible that this delay be different of 0 when the RESIZER module gets its input data from the VPORT connected to the IPIPEIF module (the offset value can be odd or even). When data are coming from the IPIPE module, it is never required to resynchronize HD and first valid data. The second function is to crop the data in the horizontal direction. When used for cropping only RSZ_SRC_HPS shall be even or null.	RW	0x0

Table 9-400. RZA_V_PHS_Y

Address Offset	0x0000 0094	Instance	ISP6P5_RESIZER
Physical Address	0x4224 0494		
Description	RESIZER A - INITIAL LUMINANCE PHASE OF VERTICAL RESIZING PROCESS When YUV422 data are output, the phase values for luma and chroma should typically be equal, i.e., $RZX_V_PHS_Y = RZX_V_PHS_C$. The following constraints apply when setting the initial vertical phases $ABS(RZX_V_PHS_Y - RZX_V_PHS_C) \leq RZX_V_DIF$. This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two luma pixels. Note that the absolute value is used, hence, the initial luma phase can be greater than the initial chroma phase or the other way around. As a reminder, the distance between two output pixels for luma is given by RZX_V_DIF .

Table 9-472. RZB_V_PHS_Y

Address Offset	0x0000 0124	Instance	ISP6P5_RESIZER
Physical Address	0x4224 0524		
Description	RESIZER B - INITIAL LUMINANCE PHASE OF VERTICAL RESIZING PROCESS When YUV422 data are output, the phase values for luma and chroma should typically be equal, i.e., $RZX_V_PHS_Y = RZX_V_PHS_C$. The following constraints apply when setting the initial vertical phases $ABS(RZX_V_PHS_Y - RZX_V_PHS_C) \leq RZX_V_DIF$. This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two luma pixels. Note that the absolute value is used, hence, the initial luma phase can be greater than the initial chroma phase or the other way around. As a reminder, the distance between two output pixels for luma is given by RZX_V_DIF .

Description	RESIZER B - RGB OUTPUT CONTROL REGISTER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												MSK1	MSK0	TYP	

Bits	Field Name	Description	Type	Reset
31:3	RESERVED		R	0x0
2	MSK1	Enables masking of the last 2 pixels This bit is used to mask the 2 last pixels at the image boundary which are affected by the YUV422 to YUV444 conversion. 0x0: output the last 2 pixels 0x1: mask the last 2 pixels (Resizer do not output them.)	RW	0x0
1	MSK0	Enables masking of the first 2 pixels This bit is used to mask the 2 first pixels at the image boundary which are affected by the YUV422 to YUV444 conversion. 0x0: output the first 2 pixels 0x1: mask the first 2 pixels (Resizer do not output them.)	RW	0x0
0	TYP	16bit/32bit output selection 0x0: 32-bit output: alpha + R + G + B (8 bit each) This mode comes with performance degradation. The maximum input frequency in this mode is 160 MHz. This due to the fact that the output is 4 bytes / pixel. 0x1: 16-bit output: R(5 bit) + G (6 bit) + B (5 bit)	RW	0x0

9.3.4.5.2 ISS ISP6P5_IPIPE Register Description
Table 9-531. IPIPE_SRC_EN

Address Offset	0x0000 0000	Instance	ISP6P5_IPIPE
Physical Address	0x4224 0800		
Description	This register is not shadowed		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED											Z				

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:1	RESERVED		R	0x0
0	EN	The start flag of the IPIPE module. When EN is 1, the IPIPE module starts a processing from the next rising edge of the VD. If the processing mode of the IPIPE module is "one shot", the EN is cleared to 0 immediately after the processing has started. 0x0: waiting 0x1: start/busy	RW	0x0

Address Offset	0x0000 0008	Instance	ISP6P5_IPIPE
Physical Address	0x4224 0808		
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							FMT3	FMT2	FMT						

Bits	Field Name	Description	Type	Reset
31:5	RESERVED		R	0x0
4	FMT3	Chroma sampling position in YUV422 to 444 This field is only valid if FMT=3 and FT2=2 0x0: 422 to 444 upsampling is processed assuming, chroma pixels are sampled at the same position as Y signals. 0x1: 422 to 444 upsampling is performed assuming chroma pixels are sampled at the center of two Y signals.	RW	0x0
3:2	FMT2	YUV processing mode This field is valid only when FMT=3 (YUV input YUV output) 0x0: Enhanced YUV mode is off. Only EdgeEnhancer, CAR, and CGS are enabled in YUV input 0x1: YUV422 input is upconverted to YUV444 422to444 is always used. GBCE, EdgeEnhancer, CAR, CGS, Histogram on YUV, BCS can be enabled. 0x3: Reserved 0x2: YUV422 input is converted to full color RGB YUVtoRGB (RGBtoRGB1 is used), Gamma (as non linear table), RGB2RGB2, 3DLUT, GBCE are used. EdgeEnhancer, CAR, CGS, Histogram on YUV, BSC can be enabled.	RW	0x0
1:0	FMT	IPIPE module datapath selection 0x0: IN: RAW BAYER OUT: YUV422 Note that the IPIPE YUV422 output goes to the RESIZER module where it can be further be converted in YUV420 or RGB format. 0x1: IN: RAW BAYER OUT: RAW BAYER The data are output after the White Balance module. It enables to bypass a large part of the IPIPE module. 0x3: IN: YUV422 OUT: YUV422 Note that the IPIPE YUV422 output goes to the RESIZER module where it can be further be converted in YUV420 or RGB format. 0x2: IN: RAW BAYER OUT: DISABLED The data are only going to BOXCAR and HISTOGRAM modules.	RW	0x0

Table 9-885. IPIPE_YUV_PHS

Address Offset	0x0000 02C8	Instance	ISP6P5_IPIPE
Physical Address	0x4224 0AC8		
Description	YUV422 down sampling register. This register controls the YUV444 to YUV422 chroma downsampling. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). IPIPE_YUV_PHS = 0 leads to pure subsampling, no filtering, cosited chroma output. IPIPE_YUV_PHS = 1 leads to (1, 1) 1 filtering, centered chroma output. IPIPE_YUV_PHS = 2 leads to (1, 2, 1) 1 filtering, cosited chroma output. IPIPE_YUV_PHS = 3 leads to (1, 3, 3, 1) 3 filtering, centered chroma output. When the chroma output is cosited, and that downsampling is enabled in the RESIZER module, one need to take care that the averager disrupts the relative phase for luma and chroma color components. The RZA_H_PHS_ADJ and RZB_H_PHS_ADJ registers need to be used to fix the disruption.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RESERVED																LP	POS						

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:2	RESERVED		R	0x0
1	LPF	121-LPF enable for chrominance samples. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). 0x0: off 0x1: on	RW	0x0
0	POS	This bit sets the output position of the chrominance sample with regards to the luma sample positions. One can choose between centered and cosited. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). The RESIZER module does not change the relative position of the chroma samples vs. the luma samples between the input and output and the chroma position at the output of the IPIPE module and at the output of the RESIZER module shall be identical. In other words, we shall have RSZ_YUV_PHS.POS = IPIPE_YUV_PHS.POS . 0x0: Cosited = same position with luminance 0x1: Centered = middle of the luminance	RW	0x0

Description	Histogram		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED												CLR	SEL		

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:2	RESERVED		R	0x0
1	CLR	Histogram memory clear. The histogram can be cleared before the start of operations. However, the clear takes 512 cycles and therefore: + if line size 512, the first line shall not be used for histogram computation. + if line size 512, ceil (512/line size) lines shall not be used for histogram computation. It's the programmer's responsibility to set the histogram computation area outside the 'clear' area. 0x0: Disable 0x1: Enable	RW	0x0
0	SEL	This bit shall be used to select which memory is used to store the histogram data. By selecting alternatively one or the other bit, one can double buffer the histogram output buffer. The 4 KB memory can either be read by the CPU or a DMA request. 0x0: Use Table 0 and 1 = 4 KBytes in the memory ISP5 map. 0x1: Use Table 2 and 3 = 4 KBytes in the memory ISP5 map.	RW	0x0

9.3.4.6.2 ISS ISP6P5_ISIF Register Description
Table 9-1084. ISIF_SYNCEN

Address Offset	0x0000 0000	Instance	ISP6P5_ISIF
Physical Address	0x4224 1000		
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED											DWEN	SYEN			

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:2	RESERVED		R	0x0
1	DWEN	Controls the storage of image sensor RAW data in memory. This bit is loaded with the timing of the internal VD signal: it becomes active starting at the lead of the VD signal that comes after 1 is written in this bit. 0x0: Disable 0x1: Enable	RW	0x0
0	SYEN	Controls ON/OFF of VD/HD output. Internal timing generator becomes active and VD/HD output begins starting when 1 is written in this bit. In case of input, VD/HD loading begins. 0x0: Disable 0x1: Enable	RW	0x0

Physical Address	0x4224 1004		
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MDFS	HLPF	INPMOD	OVF	CCDW	CCDMD	DPOL	SWEN	FIPOL	HDPOL	VDPOL	FIDD	HDVDD			

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15	MDFS	Field Status This bit indicates the status of the current FLD signal when the ISIF module is in interlaced mode. 0x0: Odd field 0x1: Even field	R	0x0
14	HLPF	Low pass filter enable. When this bit is enabled, a 3-tap ($1/4 + 1/2 Z^{-2} + 1/4 Z^{-4}$) filtering process is performed on the sensor data. 0x0: Disable 0x1: Enable	RW	0x0
13:12	INPMOD	Data input mode: 0x0: RAW data 0x1: YCbCr 16bit 0x3: Reserved 0x2: YCbCr 8bit	RW	0x2
11	OVF	ISIF module write port overflow status bit If the write port of the ISIF module overflows when writing data to SDRAM, this bit will toggle. In OMAP4430 ES1.0, an interrupt (ISIF_OVF) is added to reflect the status of this bit and avoid polling. 0x0: No overflow pending (r) No action (w) 0x1: Overflow pending (r) Clear overflow (w)	RW	0x0
10:8	CCDW	This bit enables to shift right (divide) the up-to-12-bit RAW data value when writing out to SDRAM. The effect is that the dynamic of the output signal is decreased. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x6: Reserved 0x1: 1-bit right shift out[15:0] = 00000 data[11:1] 0x7: Reserved 0x0: No shift out[15:0] = 0000 data[11:0] 0x2: 2-bit right shift out[15:0] = 000000 data[11:2] 0x4: 4-bit right shift out[15:0] = 00000000 data[11:4] 0x5: Reserved 0x3: 3-bit right shift out[15:0] = 0000000 data[11:3]	RW	0x0
7	CCDMD	Field mode: This bit selects the type of image sensor: interlaced or progressive 0x0: Progressive image sensor 0x1: Interlaced image sensor	RW	0x0
6	DPOL	Image sensor input data polarity 0x0: No change 0x1: One's complement	RW	0x0
5	SWEN	External WEN selection In case this bit and SYNCEN.DWEN are set to 1, the external WEN signal is used to store image sensor data to memory. 0x0: WEN not used 0x1: Use external WEN	RW	0x0
4	FIPO	FLD Signal Polarity 0x0: Positive 0x1: Negative	RW	0x0

Bits	Field Name	Description	Type	Reset
3	HDPOL	HD Sync Signal Polarity 0x0: Positive 0x1: Negative	RW	0x0
2	VDPOL	VD Sync Signal Polarity 0x0: Positive 0x1: Negative	RW	0x0
1	FIDD	FLD Signal Direction There shall be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes. 0x0: Input 0x1: Output	RW	0x0
0	HDVDD	VD,HD Sync Signal Direction There shall be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes. 0x0: Input 0x1: Output	RW	0x0

RESERVED																VLDC	RESERVED	MSBINVI	BSWD	Y8POS	EXTRG	TRGSEL	WENLOG	FIDMD	BT656	YCINSWP	RESERVED	RESERVED	SDRPACK		

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15	VLDC	On/off control of CPU registers re-synchronize function by VSYNC. All the others are shadowed registers, where register values are updated at V-sync timing by default. If VDLC=1, ISIF register values are updated immediately after register write just like non-shadowed registers. 0x0: Enable 0x1: Disable	RW	0x0
14	RESERVED	Reserved. Shall always be set to 0.	RW	0x0
13	MSBINVI	MSB inverse of CIN port when the data are captured to SDRAM. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Disable 0x1: Enable	RW	0x0

Bits	Field Name	Description	Type	Reset
12	BSWD	On/off control of Byte SWAP function when SDRAM capturing. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Disable 0x1: Enable (swap)	RW	0x0
11	Y8POS	Selects Y signal position when in 8bit input mode 0x0: even pixel 0x1: odd pixel	RW	0x0
10	EXTRG	Setting 1 to this register, the SDRAM address is initialized at the rising edge of FID input signal or DWEN register.	RW	0x0
9	TRGSEL	Select trigger source signal of SDRAM address initializing in case EXTRG=1. 0x0: DWEN register 0x1: FID input port	RW	0x0
8	WENLOG	Specifies the CCD valid area. 0x0: internal valid signal and WEN signal is ANDed logically. 0x1: internal valid signal and WEN signal is ORed logically.	RW	0x0
7:6	FIDMD	Specifies FID detection mode 0x0: latch the FID at the VSYNC timing 0x1: no latch the FID 0x3: Reserved 0x2: Reserved	RW	0x0
5	BT656	Selects bit width of CCIR656. This bit applies only if ISIF_REC656IF.R656ON = 1. 0x0: 8 bits 0x1: 10 bits	RW	0x0
4	YCINSWP	The ISIF module has a 16-bit interface. When 16-bit YUV data are input, the luma data (YIN7-0) are expected to be on the 8 MS bits and the chroma (CIN7-0) data are expected to be on the LS bits. This bit enables to swap the 8 MS bits with the 8 LS bits of the interface in case the luma and chroma do not come in the correct order. Refer to the top-level ISIF block diagram. 0x0: YIN7-0 = Y signal / CIN7-0 = C signal 0x1: YIN7-0 = C signal / CIN7-0 = Y signal	RW	0x0
3	RESERVED	Reserved. Shall always be set to 0.	RW	0x0
2	RESERVED	Reserved. Shall always be set to 0.	RW	0x0
1:0	SDRPACK	This bit field selects how the data are stored to SDRAM. There can be 8, 12 or 16 bits per pixel. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: 16 bits / pixel 0x1: 12 bits / pixel 0x3: Reserved 0x2: 8 bits / pixel	RW	0x0

RESERVED																YUV8P	YUV8	DFSDIR	WENE	YUV16	VDPOL	HDPOL	INTSW								

Bits	Field Name	Description	Type	Reset
31:8	RESERVED		R	0x0
7	YUV8P	8-bit YUV data unpacking to 16 bits When IPIPEIF_CFG1.INPSRC2 = 0 and IPIPEIF_CFG2.YUV16 = 1, the 8-bit YUV data are transformed into 16-bit YUV data. The way the data are unpacked from 8 bits to 16 bits is controlled by the IPIPEIF_CFG2.YUV8P register. The upper 8 bits of the 16-bit output are set to 0. 0x0: Y output on even pixels C output on odd pixels 0x1: C output on even pixels Y output on odd pixels	RW	0x0
6	YUV8	YUV 8bit mode When ISIF_CFG1.INPSRC2 = 0 and YUV16 = 1, setting this bit to 1 enables the conversion from 8bit YUV input to 16bit YUV. This register is used when the input data from the ISIF module is 8-bit YUV data. 0x0: YUV16 input 0x1: YUV 8bit input This value is not allowed if IPIPEIF_CFG1.INPSRC1 =1 and IPIPEIF_CFG1.INPSRC2 =0	RW	0x0
5	DFSDIR	DFS direction Selects the direction of dark frame subtraction. 0x0: In DFS mode VPORT IF(capture frame) - SDRAM (dark frame) In WDR mode Long Exposure: VPORT, Short Exposure: SDRAM 0x1: In DFS mode SDRAM (capture frame) - VPORT IF(dark frame) In WDR mode Long Exposure: SDRAM, Short Exposure: VPORT	RW	0x0
4	WENE	External WEN signal selection Do not use for OMAP4 and MONICA since there is not parallel interface at chip level. This register shall always be set to 0. 0x0: do not use external WEN 0x1: use external WEN	RW	0x0
3	YUV16	Data type selection. The behavior of this bitfield depends upon other register settings. The functionality is best explained with the following pseudo code: if ((CFG1.INPSRC2 ==0 CFG2.YUV16) (CFG1.INPSRC2 ==3) { data_out[15:0] = yuv[15:0] } else if (CFG1.INPSRC2 ==1 CFG2.YUV16 CFG1.UNPACK =1) { data_out[15:8] = gain_clip[7:0]; data_out[7:0] = 0; } else { data_out[15: 0] = gain_clip[15:0]; } where: o data_out[15:0] = 16bit yuv or 16bit raw data to ipipe o yuv[15:0] = 16bit yuv data from 'horizontal pixel decimator' block. o gain_clip[15:0] = 16bit raw data from 'gain' block. 0x0: 12-bit RAW data 0x1: 16-bit YUV data	RW	0x0

Bits	Field Name	Description	Type	Reset
2	VDPOL	VD Sync Polarity When input VD is active low SYNC pulse, this bit needs to be set to 1. 0x0: Positive 0x1: Negative	RW	0x0
1	HDPOL	HD Sync Polarity When input HD is active low SYNC pulse, this bit needs to be set to 1. 0x0: Positive 0x1: Negative	RW	0x0
0	INTSW	IPIPEIF interrupt source selection. This register select the interrupt source. 0x0: Start position of VD from VPORT interface 0x1: Start position of VD from ISIF module	RW	0x0

Bits	Field Name	Description	Type	Reset
0	DTUDF	Data under flow error status register. Reading 1 shows there is data under flow and at least one data is corrupted while reading from SDRAM. Writing 1 to this register clears (=0) the error (=1) status. Underflow errors are non recoverable at ISP5 level, need to do a soft reset at ISS level. The IPIPEIF_UDF interrupt is generated when an underflow happens. The interrupt avoids polling this register for errors. If ENM2MSTALL is enabled, then programmers need to ensure that the SW does not clear DTUDF[0] as this would reset the MTC read interface. DTUDF[0] can be cleared only in the on-the-fly operation where the stall mechanism will not work.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:22	AVE2LMT	AE/AWB Saturation Limit This is the value that all sub sampled pixels in the AE/AWB engine are compared to. If the data is greater or equal to this data then the block is considered saturated.	RW	0x3ff
21	OVF	H3A module overflow status bit. If the H3A module overflows it will keep sending data. The software can read this status bit during vertical blanking period to ensure that no overflow happened while writing out the data to SDRAM. There is also an interrupt at ISP5 level (H3A_OVF) which can be used to monitor this. 0x0: Read 0: No overflow pending Write 0: Status bit unchanged 0x1: Read 1: Overflow happened while writing out the data. Output data likely to be corrupted. Write 1: Clear the status bit.	RW	0x0
20	AF_VF_EN	AF Vertical Focus Enable 0x0: 4 Color Horizontal FV only 0x1: 1 Color Horizontal FV and 1 Color Vertical FV	RW	0x0
19	AEW_MED_EN	AE/AWB Median filter Enable If the median filter is enabled, then the 1st 2 and last 2 pixels in the frame are not filtered. 0x0: Disable Auto Focus median filter 0x1: Enable Auto Focus median filter	RW	0x0
18	BUSYAEAWB	Busy bit for AE/AWB	R	0x0
17	AEW_ALAW_EN	AE/AWB A-law Enable 0x0: Disable Auto exposure/white balance A-law table 0x1: Enable Auto exposure/white balance A-law table.	RW	0x0
16	AEW_EN	AE/AWB enable 0x0: Disable Auto exposure/white balance 0x1: Enable Auto exposure/white balance	RW	0x0
15	BUSYAF	Busy bit for AF.	R	0x0
14	FVMODE	Focus Value Accumulation Mode 0x0: Sum mode. 0x1: Peak mode.	RW	0x0
13:11	RGBPOS	Red, Green, and blue pixel location in the AF windows RGBPOS(0): GR and GB as Bayer pattern RGBPOS(1): RG and GB as Bayer pattern RGBPOS(2): GR and BG as Bayer pattern RGBPOS(3): RG and BG as Bayer pattern RGBPOS(4): GG and RB as custom pattern RGBPOS(5): RB and GG as custom pattern 6 and 7 are reserved This Value is only used if VF is disabled	RW	0x0

Bits	Field Name	Description	Type	Reset
10:3	MED_TH	Median filter threshold.	RW	0xff
2	AF_MED_EN	Auto Focus Median filter Enable If the median filter is enabled, then the 1st 2 and last 2 pixels in the frame are not in the valid region. Therefore the paxel start/end and IIR filter start positions should not be set within the 1st and last 2 pixels. 0x0: Disable AF median filter. 0x1: Enable AF median filter.	RW	0x0
1	AF_ALAW_EN	AF A-law table enable 0x0: Disable Auto Focus A-law table 0x1: Enable Auto Focus A-law table	RW	0x0
0	AF_EN	AF enable 0x0: Disable Auto Focus Engine 0x1: Enable Auto Focus Engine	RW	0x0

Table 9-1508. H3A_AFPAX2

Address Offset	0x0000 000C	Instance	ISP6P5_H3A
Physical Address	0x4224 140C		
Description	Setup for the AF Engine Poxel Configuration		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								AFINCH				AFINCV				PAXVC				PAXHC											

Bits	Field Name	Description	Type	Reset
31:21	RESERVED		R	0x0
20:17	AFINCH	AF Engine Column Increments Number of columns to increment in a poxel plus 1 multiplied by 2. Thus, the number of columns that can be skipped between two processed line pairs is 2-32 (even). The starting two columns in a poxel are first processed before this field is applied. This must be set so that there are at least 4 samples on a line when combined with the number of horizontal paxels. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x0
16:13	AFINCV	AF Engine Line Increments Number of lines to increment in a Poxel plus 1 multiplied by 2. Incrementing the line in a poxel is always done on a line pair due to the fact that the RGB pattern falls in two lines. If all the lines are to be processed, this field should be set to zero, and thus line count is incremented by 2 following a line pair. Thus, the number of lines that can be skipped between two processed line pairs is 0-30 (even). The starting two lines in a poxel are first processed before this field is applied. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x0
12:6	PAXVC	AF Engine Vertical Poxel Count The number of paxels in the vertical direction plus 1. The maximum number of vertical paxels in a frame should not exceed 128. The value should be set to ensure that the bandwidth requirements and buffer size are not exceeded. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x0
5:0	PAXHC	AF Engine Horizontal Poxel Count The number of paxels in the horizontal direction plus 1. It is illegal to set a number that is greater than 35 (total of 36 paxels in the horizontal direction). The minimum number of paxels should be 2 (valid range for the field is 1-35). * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x0

Table 9-1585. ISP_VP1_DLAY

Address Offset	0x0000 0028	Instance	ISS_TARGET__ISP6P5__i_IS P6_SYS3
Physical Address	Please refer to Table 9-1566		
Description	Horizontal/Vertical Delay of VP1 port		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	DELAY_SWT	RESERVED						DLV						RESERVED						DLH											

Bits	Field Name	Description	Type	Reset
31	RESERVED		R	0x0
30	DELAY_SWT	This bit changes the delay between NSF3V input VD/HD and output VD/HD. Usually, this bit is '0'. This bit is supposed to be used when NSF3V works with ISP (VP1), and IPIPEIF is in DFS/WDR mode. In this case VD must be at least one line earlier than the first valid line. 0x0: The output of VD (VD_OUT) is at the same clock as the first pixel output of the frame. The output of HD (HD_OUT) is at the same clock as the first pixel output in each line. 0x1: The VD/HD timing is controlled by DLV/DLH. VD output (VD_OUT) timing is DLV lines after VD input (VD_IN), on the same clock as HD output (HD_OUT). HD output (HD_OUT) timing is DLH pixel clocks after HD input (HD_IN).	RW	0x0
29:24	RESERVED		R	0x0
23:16	DLV	Vertical Delay of VP1 port from VS_IN to VD_OUT. This field is only used if DELAY_SWT=='1', and ignored if DELAY_SWT=='0'. This register is latched at VS. If DELAY_SWT is '1', after number of lines specified here following VD_IN, VD_OUT is output. This value should be equal to or smaller than NSF3V line latency for meaningful operation. The only possible case that this field is used is when NSF3V is used with ISP, and IPIPEIF is in DFS or WDR mode. A value between 0 and 3 should be specified for TB_BORDER=00 or 10 case. A value between 0 and 17 should be specified for TB_BORDER=01 or 11 case. Since there is DLV lines between VD and the first valid line, the downstream modules need to be programmed accordingly.	RW	0x0
15:8	RESERVED		R	0x0
7:0	DLH	This field is only used if DELAY_SWT=='1', and ignored if DELAY_SWT=='0'. VP1 port horizontal delay from HS_IN (derived from HD_IN) to HD_OUT, which affects the cycles between HD_OUT and first valid pixel. This register is latched at VS. The meaning of this value changes depending on the input format (ISP_NSF3V_MODESET.INPMOD). For YCbCr-16bit (ISP_NSF3V_MODESET.INPMOD==1) The maximum DLH value allowed is 8. If DLH=8, HD output is at the same clock as the first pixel output in each line. If DLH=8, HD output is (8-DLH) clock before the first pixel output. For Bayer input or YCbCr-8bit input (ISP_NSF3V_MODESET.INPMOD==0 or 2) Maximum DLH allowed is 16. If DLH=16, HD output is at the same clock as the first pixel output in each line. If DLH=16, HD output is (16-DLH) clock before the first pixel output.	RW	0x0

Table 9-1725. GLBCE_MODE

Address Offset	0x0000 0004	Instance	ISP6P5_GLBCE
Physical Address	0x4225 1004		
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												OST			

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	OST	One shot mode or continuous mode. One shot mode turns itself off after each frame. Note that this bit only controls the enable signal, and does not revert the statistics to the default status. To revert the cache content to the default status, you either need to SW reset GLBCE module, or load the default value from SDRAM to cache memory. To perform the latter option, default cache table needs to be copied to SDRAM before hand. 0x0: Continuous mode. GLBCE module keep running after each frame until the enable bit is turned off. 0x1: One shot mode. GLBCE turns off it self at the beginning of each frame.	RW	0x0

Table 9-1727. GLBCE_CONTROL0

Address Offset	0x0000 0008	Instance	ISP6P5_GLBCE
Physical Address	0x4225 1008		
Description	GLBCE Configuration Port GLBCE Control Register 0 (control_0)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED												CCTL	MB	RESERVED	ONOFF

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:5	RESERVED		R	0x0
4	CCTL	Color Control (CCTL) - Enabling this processing will result in more accurate colors processing. The color correction algorithm is required on gamma corrected sources It reduces the saturation in dark areas when they are being amplified, and saturates bright parts when they get darker. This bit is reserved and tied zero in ISS6 0b: Disable color correction 1b: Enable color correction	R	0x0
3	MB	Max Bayer Type- Use this bit to select the algorithm used for calculating intensity. 0b: Algorithm 1 1b: Algorithm 2 (Recommended) 0x0: 0b: Algorithm 1 0x1: 1b: Algorithm 2 (Recommended)	RW	0x1
2:1	RESERVED	These bits are read only. Controls the storage of image sensor RAW data in memory. This bit is loaded with the timing of the internal VD signal: it becomes active starting at the lead of the VD signal that comes after 1 is written in this bit.	R	0x0
0	ONOFF	GLBCE On/Off - This bit turns GLBCE processing ON and OFF. When GLBCE is OFF, the video data passes to the output without any changes. Disabling GLBCE using this bit is equivalent to setting the Strength parameter to 0. Many internal modules run in idle mode when this bit is 0. The Latency Delays between the input and the output signals are the same in both ON and OFF modes. 0b: Disable GLBCE processing 1b: Enable GLBCE processing 0x0: Disable 0x1: Enable	RW	0x0

Table 9-1735. GLBCE_VARIANCE

Address Offset	0x0000 0018	Instance	ISP6P5_GLBCE
Physical Address	0x4225 1018		
Description	GLBCE Configuration Port Affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). If this parameter is set to zero, the sensitivity to the small areas is maximal. The transform becomes more local. When the parameter is set to 0xFF the transform deemphasizes small local details, and transform becomes more global e.g. the sky at the top of the frame can affect flowers at the bottom of the frame.		

Table 9-1735. GLBCE_VARIANCE (continued)

Type		RW																													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 9-1741. GLBCE_SLOPE_MAX

Address Offset	0x0000 0024	Instance	ISP6P5_GLBCE
Physical Address	0x4225 1024		
Description	GLBCE Configuration Port Slope Max Limit Register (slope_max)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SLOPEMAXLIMIT															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED		R	0x0
7:0	SLOPEMAXLIMIT	Slope Max Limit - Slope Max Limit is used to restrict the slope of the tone-curve generated by GLBCE. When Slope Max Limit parameter is set to 0xFF, the tone curve slope, generated by GLBCE is not limited (maximum slope 15). When this value is set to 00 GLBCE will not generate the tone-curve with slope greater than 16/15 (48°). Intermediate values of Slope Limit are linear interpolation between minimum and maximum values. Recommended Slope Max Limit range is 20h-60h. For noisy images less value should be used.	RW	0x28

RESERVED																AUTOSIZE	AUTOPOS	FCMODE	RESERVED	VSPOL	HSPOL										

Bits	Field Name	Description	Type	Reset
31:8	RESERVED		R	0x0
7	AUTOSIZE	This value is read only. GLBCE in ISP6 nver use Auto-size mode. 0x0: Auto size off. The GLBCE core will use frame_width, frame_height ports values. 0x1: Auto size on. The GLBCE core will calculate the frame geometry based on the active line and field signals. The size of current frame will be used for the estimation of the next frame. The Frame size will be updated when the Field signal toggles.	R	0x0
6	AUTOPOS	This value is read only. GLBCE in ISP6 always runs in Auto Position mode. 0x0: Auto Position off 0x1: Auto Position On	R	0x1
5:4	FCMODE	Field Correction Mode 0x0: Internal field signal will be the same as external field signal. Internal generation of field is not available in this mode 0x1: Adjust field signal with v_sync 0x2: Adjust field signal with active line	R	0x0
3:2	RESERVED		R	0x0
1	VSPOL	Vertical Sync Polarity This value is read only. The SWITCH block always convert the polarity to rising edge active. 0x0: Rising edge active 0x1: Falling edge active	R	0x0
0	HSPOL	Horizontal Sync Polarity This value is read only. The SWITCH block always convert the polarity to rising edge active. 0x0: Rising edge active 0x1: Falling edge active	R	0x0

9.4 ISS Still Image Coprocessor (SIMCOP)

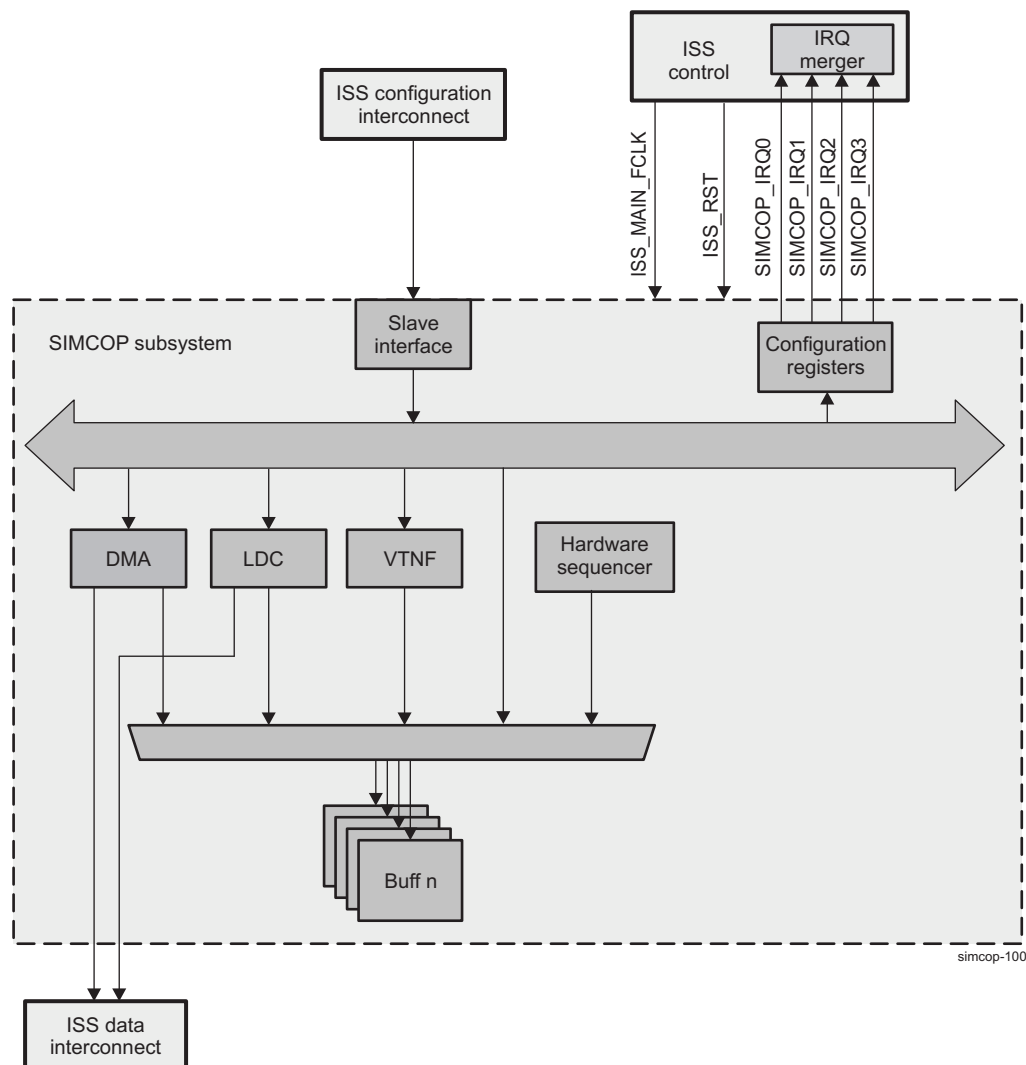

This section gives a high-level description of the ISS Still Image Coprocessor (SIMCOP) in the device. For a high-level description of ISS level, see [Section 9.1, ISS: Overview](#).

9.4.1 ISS SIMCOP Overview

The SIMCOP subsystem is designed to process image data. SIMCOP is a macroblock-based memory-to-memory processing engine. It fetches macroblocks from system memory and stores them into local memories. Different accelerators take the fetched data, perform processing, and send the processing outcome back to local memories. From there the data could be further processed by other accelerators or sent back to system memory. The SIMCOP needs an external central processing unit (CPU) to perform high-level control tasks and configurations.

Figure 9-174 shows a block diagram of the SIMCOP subsystem.

Figure 9-174. SIMCOP Subsystem Overview

The ISS SIMCOP subsystem consists of:

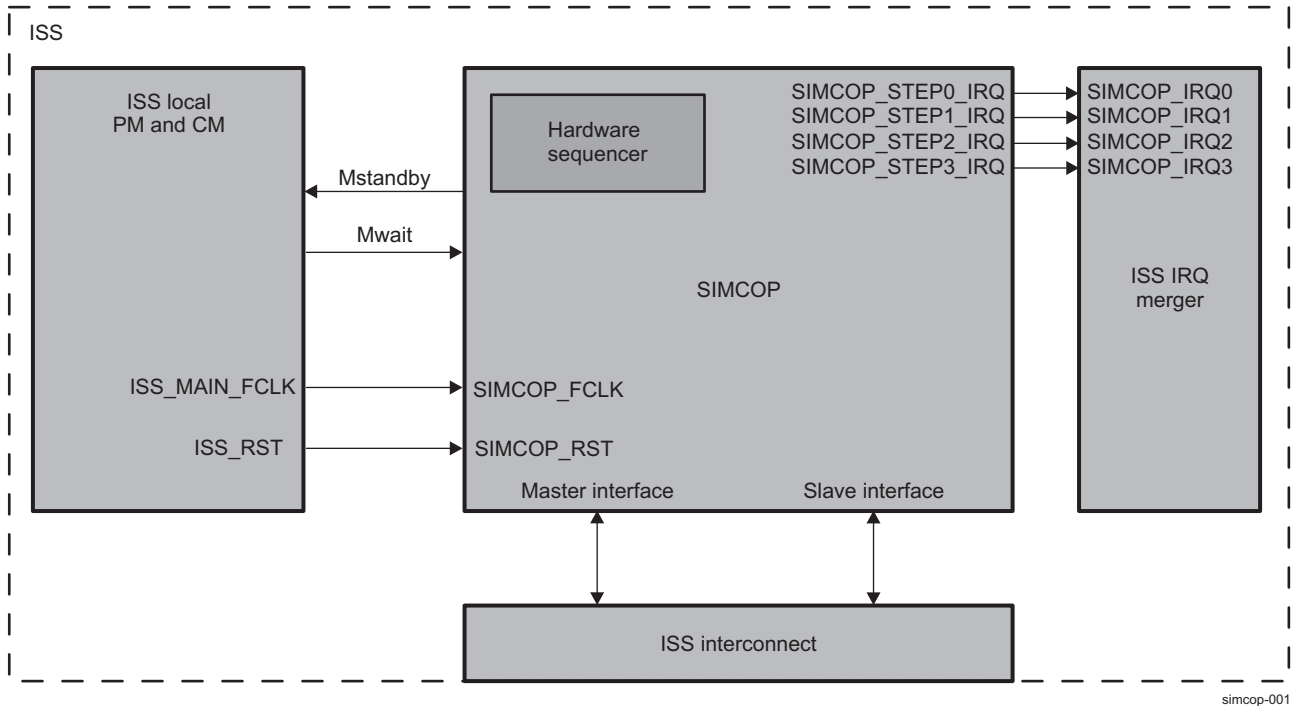

- Temporal Video Noise Filter (VTNF) - performs temporal video noise filtering.
- Hardware Sequencer - for low-level sequencing tasks and memory operations
- Direct memory access (DMA) controller – Data transfers from SIMCOP memories to system memory or from system memory to SIMCOP memories

- Lens distortion correction (LDC) - rotation, affine warp and perspective correction

9.4.1.1 ISS SIMCOP Integration

The SIMCOP subsystem is connected to the rest of the system through the ISS local interconnect. Figure 9-175 shows the integration of the SIMCOP subsystem in the ISS.

Figure 9-175. SIMCOP Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see , *Clock Management in , Power, Reset, and Clock Management.*

This section gives an overview of typical uses of the module. See , *Power, Reset, and Clock Management* for more information and settings of the PRCM relationship to ISS clocks and resets.

Table 9-2607 lists the Integration Attributes.

Table 9-2607. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SIMCOP	PD_EVE3	L3_MAIN via ISS interconnect

Table 9-2608 lists the clocks and resets values.

Table 9-2608. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SIMCOP	SIMCOP_FCLK	ISS_MAIN_FCLK	ISS	Functional clock. It is used by all ISS submodules and ISS top-level resources.

Resets				
--------	--	--	--	--

Table 9-2608. Clocks and Resets (continued)

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SIMCOP	SIMCOP_RST	ISS_RST	ISS	ISS and SIMCOP global reset.

Table 9-2609 lists the hardware resets.

Table 9-2609. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
SIMCOP	SIMCOP_STEP_0_IRQ	SIMCOP_IRQ0	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP_1_IRQ	SIMCOP_IRQ1	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP_2_IRQ	SIMCOP_IRQ2	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP_3_IRQ	SIMCOP_IRQ3	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer

For more information about interrupt requests, see *Interrupt Merger*.

9.4.1.2 ISS SIMCOP Functional Description

9.4.1.2.1 ISS SIMCOP Local Power and Clock Management

9.4.1.2.1.1 ISS SIMCOP Local Clock Management

SIMCOP receives one functional from ISS (ISS_MAIN_FCLK).

A clock-enable signal provided externally is used. Multiple subdomains exist internally to reduce dynamic power consumption. This feature does not require intervention by the PRCM module. For high-level description of the SIMCOP clock domain and configuration inside ISS, see , *ISS Clock Domains* and , *ISS Clocks*.

Moreover, at high level the functional clock of ISS SIMCOP submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the [SIMCOP_CLKCTRL](#) register (see [Table 9-2610](#)).

For software to enable a submodule:

- Software sets the appropriate bit in the [SIMCOP_CLKCTRL](#) register.
- Hardware enables the submodule functional and interface clocks.
- Hardware connects the configuration port of the submodule to the coprocessor bus.
- Hardware sets the appropriate bit in the [SIMCOP_CLKCTRL](#) register. Software must check if this bit is set before accessing the submodule.

[Table 9-2610](#) shows the ISS SIMCOP clock control register settings.

Table 9-2610. ISS SIMCOP Clock Control Register Settings

Module Name	Bit Field Name	Description
VTNF	SIMCOP_CLKCTRL [9] VTNF	Writing 0x1 enables the module
LDC	SIMCOP_CLKCTRL [1] LDC	Writing 0x1 enables the module
DMA	SIMCOP_CLKCTRL [0] DMA	Writing 0x1 enables the module

For software to shut down a submodule:

- Software ensures that the submodule is idle. Mainly:
 - The submodule must not generate new events.
 - The submodule must not have any pending events.
 - For initiators, the submodule must stop interconnect transaction generation.
- Software clears the appropriate bit in the [SIMCOP_CLKCTRL](#) register.
- Hardware disconnects the configuration port of the module from the coprocessor bus, no more accesses are routed to the submodule. Ongoing transactions are finished (hardware stays in this state as long as required).
- For initiators, hardware waits until there are no more outstanding transactions:
 - The SIMCOP DMA provides an MStandBy signal used for that purpose.
 - The SIMCOP LDC provides an MStandBy signal used for that purpose.
- Hardware cuts the submodules clock.
- Hardware clears the appropriate [SIMCOP_CLKCTRL](#) registers.

SIMCOP submodules support autogating. They can gate their functional and interface clock internally based on functional requirements. This feature can be disabled for debug or power consumption measurement purposes.

9.4.1.2.1.2 Local Clock Autogating

The SIMCOP subsystem modules support autogating. They can gate their functional and interface clock internally based on functional requirements. This feature can be disabled. [Table 9-2611](#) summarizes what modules support autogating control and which control bit is used.

Table 9-2611. Autoclock Gating Bit Control

SIMCOP resource	Autogating override
SIMCOP top-level resources	NA
SIMCOP DMA	NA
VTNF	VTNF_CTRL[10] AUTOGATING

9.4.1.2.1.3 ISS SIMCOP Power Management

The SIMCOP supports the STANDBY power management protocol. It is used by the SIMCOP to indicate when it has no more interconnect transactions to perform. This information is used at the ISS level to control the SIMCOP and ISS shut-down sequence. The SIMCOP does not have any internal wake-up events. DISCONNECT and IDLE protocols are not supported.

The typical SIMCOP shut-down sequence is:

- Software disables all SIMCOP submodules. This ensures the SIMCOP does not:
 - Generate any traffic on its master port; SIMCOP asserts the MStandby signal.
 - Generate new events (IRQs).
- Software clears all pending events at the SIMCOP level; all interrupt lines become inactive.
- Software initiates the SIMCOP shut-down sequence by writing the appropriate bit at the ISS level.
- ISS hardware:
 - Disconnects the SIMCOP configuration port. Any access attempts to the SIMCOP are blocked at the ISS level. The DISCONNECT protocol is handled at the ISS level; the SIMCOP does not provide any handshake signals to support it.
 - Waits until MStandby from SIMCOP is asserted (always true in a normal case because SIMCOP submodules are inactive)
 - Asserts the SWait input of SIMCOP
 - Cuts the SIMCOP clock

The typical SIMCOP enable sequence is:

- Software initiates the SIMCOP enable sequence by writing the appropriate bit at the ISS level.
- ISS hardware:
 - Enables the SIMCOP clock
 - Deasserts the SWait input of SIMCOP
 - Connects the SIMCOP configuration port

9.4.1.2.2 ISS SIMCOP Reset

SIMCOP supports 2 reset sources:

- Hardware reset from PRCM
- Software reset from [SIMCOP_HL_SYSCONFIG\[0\] SOFTRESET](#)

The HW reset is unconditional and resets SIMCOP as well as its sub-modules. It typically requires a complete device reset as the OCP and PM protocol integrity is not guaranteed.

The SIMCOP module is able to accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset. Unlike HW reset, SW reset can safely be performed during SIMCOP operation: OCP and STANDBY protocol integrity is guaranteed by HW. This is done by the sequence below:

- Disable all SIMCOP DMA channels.
- Select smart standby mode for LDC and SIMCOP DMA
- Set [SIMCOP_HL_SYSCONFIG\[0\] SOFTRESET](#) to "1"
- Read [SIMCOP_HL_SYSCONFIG\[0\] SOFTRESET](#) back until the returned value is 0.

The SIMCOP HW does the following when a SW reset command is received:

- Stop accepting new OCP commands on its slave port by stalling the port on a clean transaction boundary.
- Wait until all OCP responses have been returned to the slave port. This also includes the response of the SW reset command itself.
- LDC will stop issuing OCP requests immediately and will assert Standby when it receives responses of all the requests. Internal processing will be stopped once the ongoing block processing is done.
- DMA will complete any ongoing channel transfer and will go into standby state.

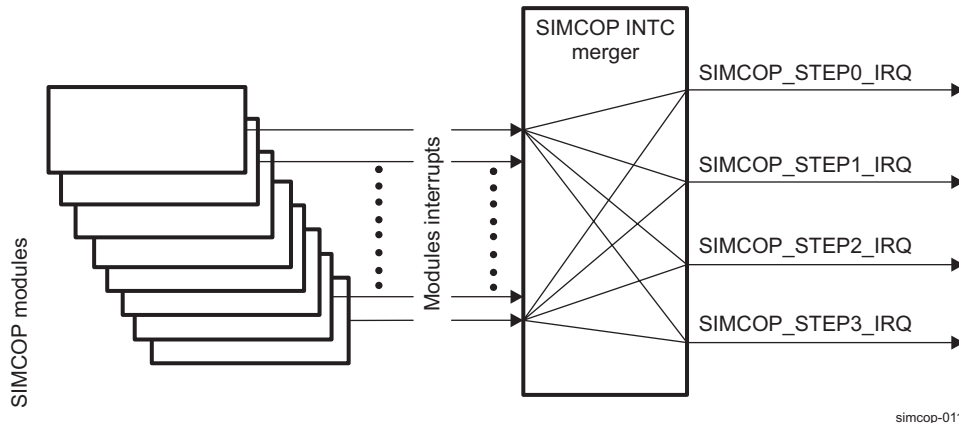

SIMCOP then performs the internal reset. A SW reset at SIMCOP level is seen as a HW reset for SIMCOP sub-modules. However, as SIMCOP has isolated sub-modules by stalling the OCP ports, no protocol violation can occur.

SW reset does not directly affect the state of the power management handshake signals (i.e. the protocol handshake is preserved).

9.4.1.2.3 ISS SIMCOP Interrupt Merger

SIMCOP interrupts are merged at the SIMCOP subsystem level into four interrupts as shown in [Figure 9-176](#).

Figure 9-176. SIMCOP Interrupt Merger Overview

These four outputs interrupts can be configured using the [SIMCOP_HL_IRQENABLE_SET_i](#) and [SIMCOP_HL_IRQENABLE_CLR_i](#) (i = 0 to 3, corresponding to output interrupt) to enable or disable interrupt mask for each interrupt output. Software can poll the value of interrupt before masking [SIMCOP_HL_IRQSTATUS_RAW_i](#) and after masking [SIMCOP_HL_IRQSTATUS_i](#).

Software can configure how outputs interrupts are generated by using the [SIMCOP_CTRL\[I\] IRQi_MODE](#) (i = 0 to 3) bit field(s):

- 0x0: OR – The interrupt is asserted when one of the selected events has occurred
- 0x1: AND – The interrupt is asserted when all selected events have occurred

[Table 9-2612](#) shows how interrupts are mapped on the [SIMCOP_HL_IRQSTATUS_RAW_i](#), [SIMCOP_HL_IRQSTATUS_i](#), [SIMCOP_HL_IRQENABLE_SET_i](#) and [SIMCOP_HL_IRQENABLE_CLR_i](#) registers.

Table 9-2612. ISS SIMCOP Interrupts

Bit	Name	Description
0	SIMCOP_DMA_IRQ0	Interrupt triggered by SIMCOP DMA
1	LDC_FRAME_IRQ	This event is triggered by LDC when a full frame has been processed
8	VTNF_IRQ	Interrupt triggered by VTNF when one processed block is done
9	LDC_BLOCK_IRQ	This event is triggered by LDC when a macro-block has been processed
10	SIMCOP_STEP0_IRQ	Event triggered when a SIMCOP context is activated by the HW sequencer
11	SIMCOP_STEP1_IRQ	
12	SIMCOP_STEP2_IRQ	
13	SIMCOP_STEP3_IRQ	
14	DONE_IRQ	Event triggered when the HW sequencer finishes the sequence: - the sequence step counter has reached the limit - All accelerator and DMA events for the last sequence step have been received.
16	OCP_ERR_IRQ	An error has been received on the SIMCOP master port on L3 interconnect.
18	SIMCOP_DMA_IRQ1	Interrupt triggered by SIMCOP DMA
19	CPU_PROC_START_IRQ	This interrupt is used when CPU data processing is used in a macroblock processing pipeline. When CPU receives this IRQ, data for ready to be processed. When CPU is done with processing it acknowledges by setting the SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE bit. The interrupt is cleared as usual.

9.4.1.2.4 ISS SIMCOP Modules Description

This section provides links to each subchapter for each submodule in the ISS SIMCOP module.

The ISS module provides a unique ISS_MAIN_FCLK for all the submodules inside the SIMCOP, see [Section 9.4.1.2.1.1](#).

For information about hardware and software resets for each module, see [Table 9-2612](#).

For interrupt request information for each module, see [Table 9-2609](#).

The ISS SIMCOP consists of the following submodules:

- Hardware Sequencer and buffers, for more information, see [Section 9.4.2](#).
- DMA, for more information, see .

9.4.1.3 ISS SIMCOP Programming Models

9.4.1.3.1 Global Initialization

9.4.1.3.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the ISS SIMCOP module is to be used for the first time after a device reset. This initialization of the surrounding modules is based on the integration of the ISS SIMCOP.

Table 9-2613. ISS SIMCOP Global Initialization of Surrounding Modules

Surrounding Modules	Comments
ISS local PM and CM	Module interface and functional clocks must be enabled. For more information, see Section 9.4.1.2.1 , <i>ISS SIMCOP Local Power and Clock Management</i> .

9.4.1.3.1.2 ISS SIMCOP Module Global Initialization

This procedure initializes the ISS SIMCOP module after a power-on or software reset.

Table 9-2614. ISS SIMCOP Global Initialization

Step	Register/ Bitfield / Programming Model	Value
Execute software reset	SIMCOP_HL_SYSCONFIG [0] SOFTRESET	0x1
Wait until reset completed?	SIMCOP_HL_SYSCONFIG [0] SOFTRESET	0x0
Configure submodules interface and functional clock	SIMCOP_CLKCTRL [7:0]	xxx
Interrupt configuration		
Set interrupt enable bit for the submodules	SIMCOP_HL_IRQENABLE_SET_i [7:0]	xxx

9.4.1.3.2 ISS SIMCOP Operational Modes Configuration

9.4.1.3.2.1 Interrupts

To unmask an interrupt for generation of the SIMCOP_IRQi output interrupts, software must set the corresponding bit of the [SIMCOP_HL_IRQENABLE_SET_i](#) (I = 0 to 3) register to 1.

Example 1:

SIMCOP_IRQ1 is generated when VTNF_IRQ is generated:

- [SIMCOP_HL_IRQENABLE_SET_i](#)[8] VTNF_IRQ = 0x1 (I = 1)
- [SIMCOP_CTRL](#)[1] IRQ1_MODE = 0x0

Example 2:

SIMCOP_IRQ3 is generated when DMA_IRQ is generated:

- [5] IMX_A_IRQ = 0x1 (I = 3)
- [SIMCOP_HL_IRQENABLE_SET_i](#)[18] SIMCOP_DMA_IRQ1 = 0x1 (I = 3)
- [SIMCOP_CTRL](#)[3] IRQ3_MODE = 0x1

To mask an interrupt for generation of the SIMCOP_IRQ_i output interrupts, software must clear the corresponding bit of the SIMCOP_HL_IRQENABLE_CLEAR_i (I = 0 to 3) register by setting it to 0.

When an event occurs, the corresponding bit in the SIMCOP_HL_IRQSTATUS_RAW_i (I = 0 to 3) register is set regardless of whether or not the event has been enabled. Bits in the SIMCOP_HL_IRQSTATUS_i (I = 0 to 3) registers are only set when an enabled event occurs. Software can clear a pending event by setting the appropriate bit in the SIMCOP_HL_IRQSTATUS_i (I = 0 to 3) register.

9.4.1.4 ISS SIMCOP Registers Manual

9.4.1.4.1 SIMCOP Instance Summary

Table 9-2615 summarizes the SIMCOP instance.

Table 9-2615. SIMCOP Instance Summary

9.4.2 ISS SIMCOP Hardware Sequencer and Buffers Module

This section describes the hardware sequencer and buffers in the still image coprocessor (SIMCOP) subsystem.

9.4.2.1 ISS SIMCOP Hardware Sequencer and Buffers Overview

The SIMCOP hardware sequencer control all the modules included in the SIMCOP subsystem with their memories.

[Figure 9-177](#) shows an overview of the hardware sequencer and buffers in the SIMCOP subsystem.

Figure 9-177. Hardware Sequencer and Buffers in the SIMCOP Subsystem

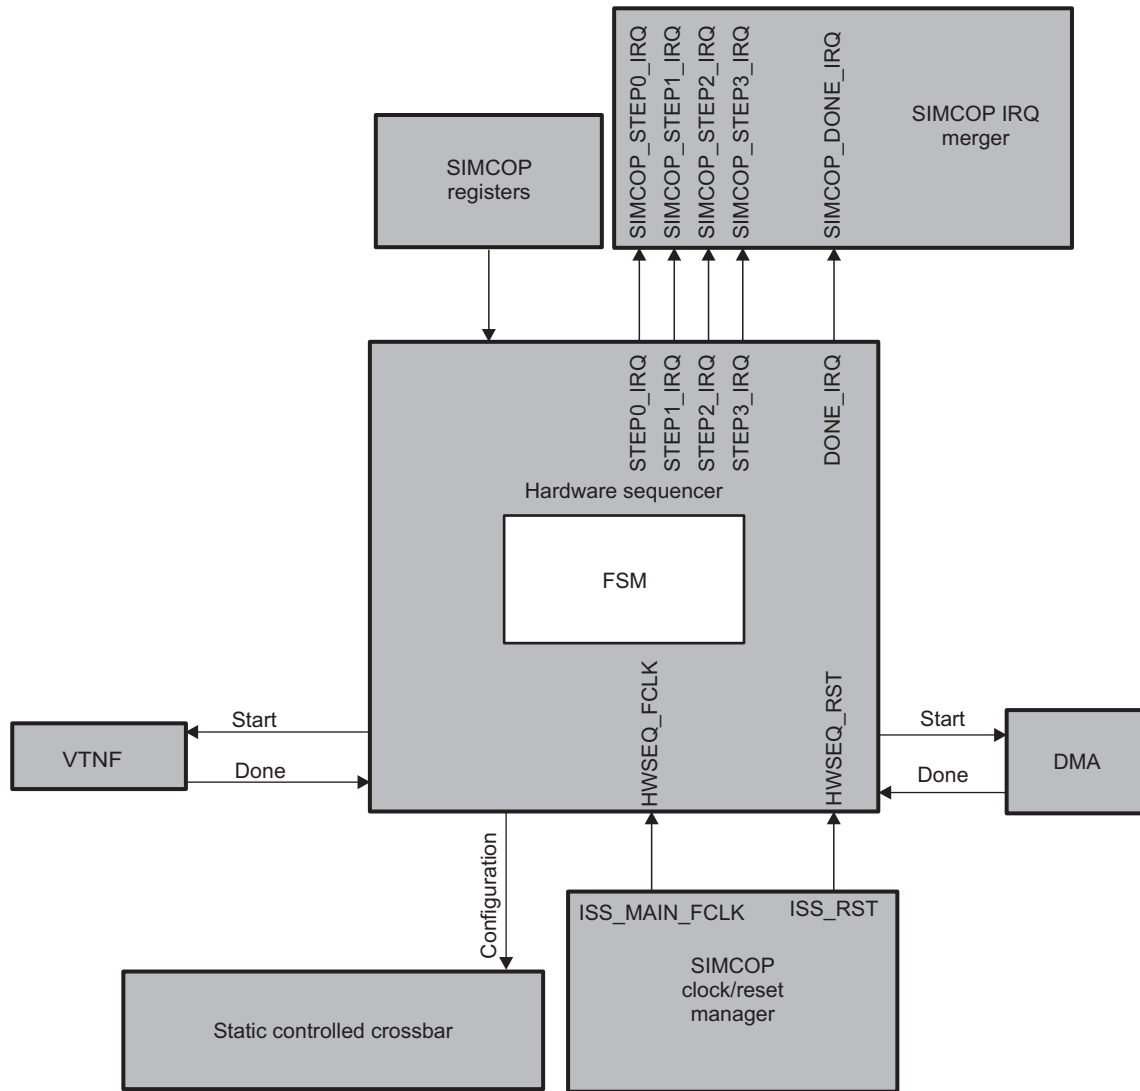

- Hardware acceleration for low-level sequencing tasks:
 - Synchronizes with DMA and VTNF
 - Supports 4 memory crossbar contexts
- Power management support

9.4.2.2 ISS SIMCOP Hardware Sequencer and Buffer Integration

The hardware sequencer and buffers module is part of the SIMCOP subsystem in the ISS.

[Figure 9-178](#) shows the integration of the hardware sequencer and buffers in the SIMCOP subsystem.

Figure 9-178. Hardware Sequencer and Buffer Integration

hwseq-011

Table 9-2639 lists the integration attributes, Table 9-2640 lists the clocks and resets, and Table 9-2641 lists the hardware requests.

9.4.2.3 ISS SIMCOP Hardware Sequencer and Buffers Functional Description

9.4.2.3.1 ISS SIMCOP Hardware Sequencer and Buffers Software Reset

For information about how to perform a software reset, see [Section 9.4.1.2.2, Software Reset](#).

9.4.2.3.2 ISS SIMCOP Hardware Sequencer and Buffers Power Management

For more information about power management, see [Section 9.4.1.2.1.3, ISS SIMCOP Power Management](#).

9.4.2.3.3 ISS SIMCOP Hardware Sequencer and Buffer Interrupt Requests

This module sends four interrupts to the ISS top level. For more information about interrupt management, see [Section 9.4.1.2.3, Interrupt Merger](#).

9.4.2.3.3.1 Static Crossbar

The static crossbar connect SIMCOP modules to the SIMCOP memories as shown in [Figure 9-179](#).

Figure 9-179. SIMCOP Static Crossbar Overview

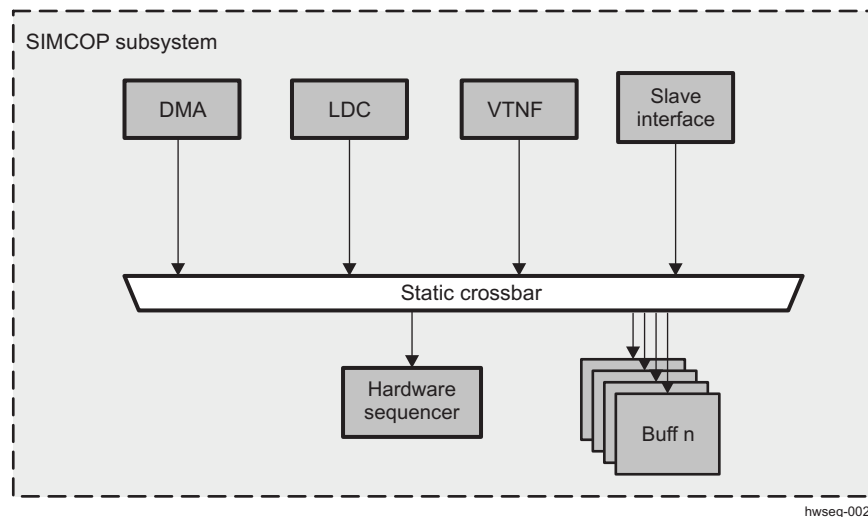

Image buffers are used to store the data to be processed and processing results. Those memories can be accessed by the SIMCOP DMA, SIMCOP bus, and SIMCOP modules. [Table 9-2642](#) shows possible connections in the SIMCOP static crossbar. For example, the DMA Freq port could access image buffer a when `SIMCOP_HWSEQ_SWITCH_i[2:0] IMBUFF_E = 0x1` ($i = 0, 1, 2, \text{ or } 3$ corresponds to the active context).

The SIMCOP supports multiple contexts for the configuration of those memories. Software or the hardware sequencer can activate different contexts.

The BITSTREAM data flow is asynchronous from the macroblock pipeline, therefore, it supports dynamic buffer switching logic.

Table 9-2642. Static Crossbar Control Summary

Memory	Register (SIMCOP_HWSEQ_STEP_SWITCH_i and SIMCOP_HWSEQ_STEP_CTRL2_i)	Value		
		Bus	DMA	VTNF
IMBUFF e	[18:16] IMBUFF_E	0	1	8
IMBUFF f	[22:20] IMBUFF_F	0	1	8
IMBUFF g	[27:24] IMBUFF_G	0	1	8
IMBUFF h	[31:28] IMBUFF_H	0	1	8

9.4.2.3.3.2 Image Buffers

Image buffers are 4 banks × 256 × 32 bits (4K bytes) working memories used by the SIMCOP modules to perform image processing operations. Image buffers are shared between the DMA, VTNF, and SIMCOP bus accesses. All initiators cannot access the image buffers simultaneously.

Switches are controlled by the hardware sequencer or an external initiator through register configuration. Data is always organized in little endian form.

One or multiple image buffers can be attached to a given accelerator port by configuring the appropriate bits in the `SIMCOP_HWSEQ_STEP_SWITCH_i` registers.

The image buffer address offsets to different busses shown in [Table 9-2643](#) is controlled using the appropriate `SIMCOP_HWSEQ_STEP_CTRL_i` register bit fields.

Table 9-2643. Image Buffer Address Offsets

Port	OFST	0x0000	0x1000	0x2000	0x3000	0x4000	0x5000	0x6000	0x7000
DMA	0					E	F	G	H
	1				E	F	G	H	
	2			E	F	G	H		
	3		E	F	G	H

Figure 9-180. Image Buffer Width Translation

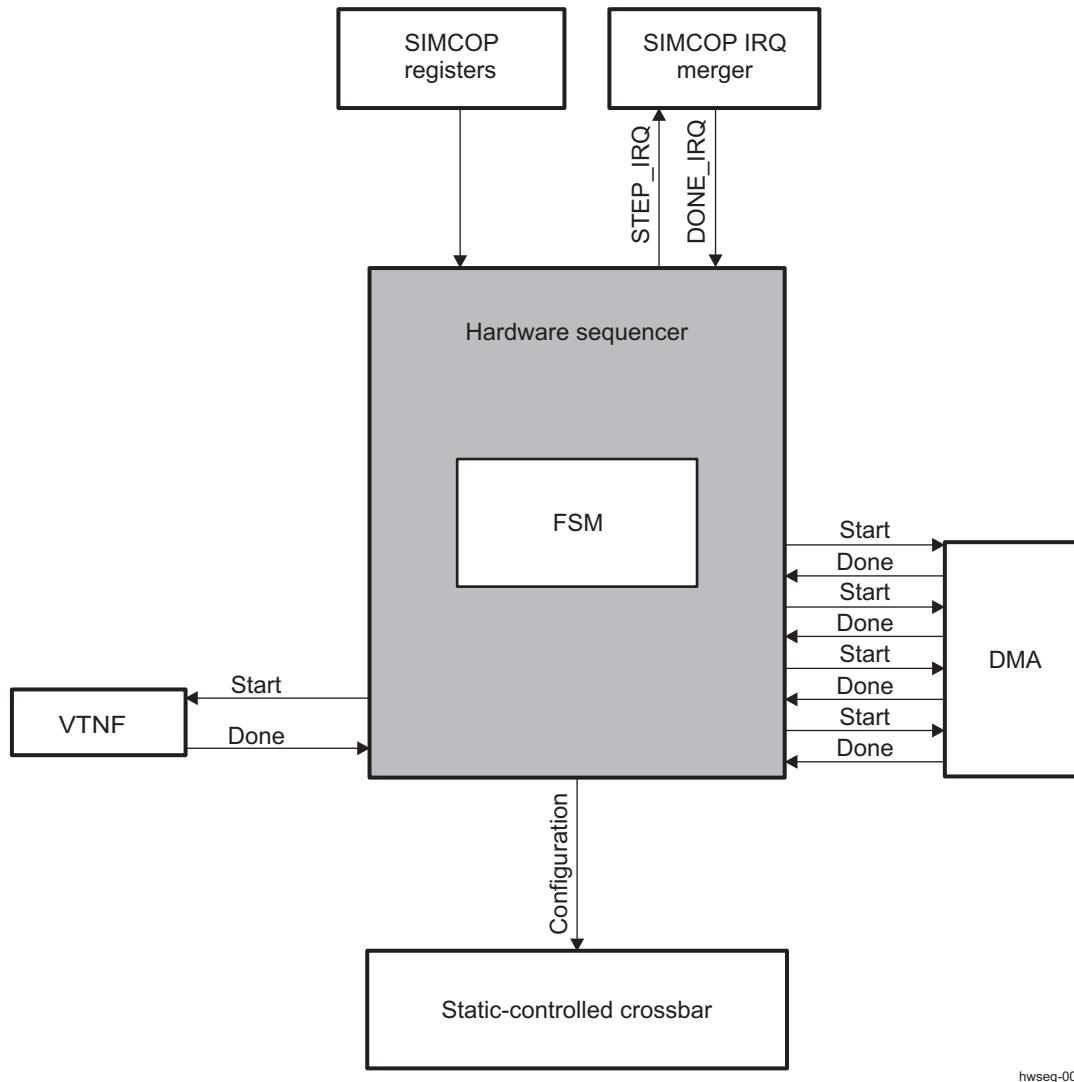

hwseq-003

9.4.2.3.4 ISS SIMCOP Hardware Sequencer

The SIMCOP typically processes a full frame on a macroblock-by-macroblock basis. The SIMCOP modules and the DMA controller trigger an interrupt when they have completed a macroblock. This event can either trigger an interrupt to an external initiator (CPU) (manual mode) or trigger a context switch and resume DMA/SIMCOP module processing. Typically, initiator intervention is needed to fill the macroblock pipeline (called pipe-up, that is, the first n macroblocks of an image) and to flush the macroblock pipeline (called pipe-down, that is, the last n macro-blocks of an image). Automatic sequencing mode is typically used for the rest of the image.

Figure 9-181 depicts the SIMCOP hardware sequencer overview.

Figure 9-181. SIMCOP Hardware Sequencer Overview

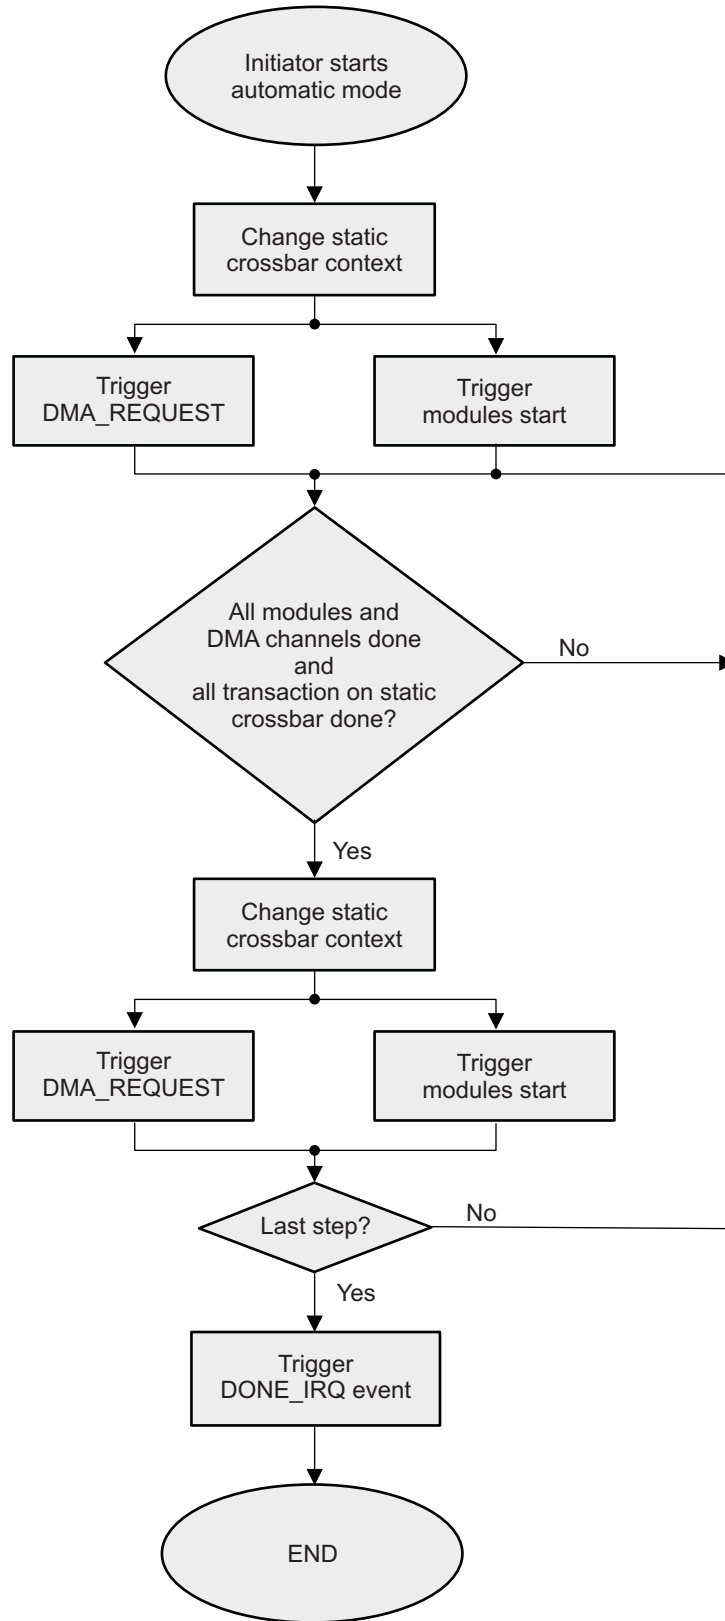

hwseq-008

The hardware sequencer can automatically execute a predefined number of sequencing steps without software intervention. This is called automatic operation. Automatic operation can also be used for pipeline filling and flushing with some limited software intervention. During automatic operation, the hardware sequencer controls the generation of START/DONE pulses and the connections in the static controlled crossbar. Software can take control over some resources while the hardware sequencer is running. This is called hardware sequencer override.

9.4.2.3.4.1 Automatic Operation

Figure 9-182 shows the flow diagram executed by the hardware sequencer.

Figure 9-182. Hardware Sequencing Example

hwseq-009

The external initiator configures the different SIMCOP modules and DMA channels. When this is complete, it enables the hardware sequencer. This resets the internal state of the hardware sequencer (pending events and context switch counter).

It starts by running sequence step `SIMCOP_HWSEQ_CTRL[12:11] STEP`:

- Clear all pending completion events that have been selected for Step 0 in the hardware sequencer. Note: This does not affect the `SIMCOP_IRQSTATUS` register.
- Apply step `SIMCOP_HWSEQ_CTRL[12:11] STEP` configuration to the static crossbar
- Start DMA transfers. Multiple channels can be enabled sequentially (that is, YUV4:2:0 data transfers or SIMCOP-SDRAM followed by SDRAM-SIMCOP) by using the SIMCOP DMA linking feature.
- Start hardware accelerators. The list of accelerators to start can be selected by software using the `SIMCOP_HWSEQ_STEP_CTRL_i[7:0] *_SYNC` register

The hardware sequencer then waits for completion of events from the selected SIMCOP modules and SIMCOP DMA channels.

The hardware sequencer also ensures that all SIMCOP memory accesses requested by the accelerators and DMA channels enabled for the synchronization step have completed. This condition prevents data corruption due to early switching.

Steps can be chained to define the sequence to execute. Steps are started until the step counter reaches the limit defined by software. When the last step has completed, a `DONE_IRQ` event is triggered.

The SIMCOP can execute one hardware sequence at the time. However, software can be used to execute multiple independent sequences in parallel (that is, two unrelated macroblock pipelines) using the override feature.

The hardware sequencer has no specific support for macroblock pipeline filling (pipe-up) or flushing (pipe-down). It needs some software intervention.

The hardware sequencer supports sequences composed of up to four steps. Longer sequences require software intervention.

Figure 9-182 illustrates the hardware sequencer operation.

Figure 9-183. Hardware Sequencer Operation Example

hwseq-010

The example involves utilization of two SIMCOP modules (or DMA channels) that are synchronized using the hardware sequencer. A total of five sequencing steps are executed (`SIMCOP_HWSEQ_CTRL[31:6] HW_SEQ_STEP_COUNTER=5`). The sequence is 2 steps long and starts with Step 1. Those two steps are configured using the `SIMCOP_HWSEQ_STEP_*_i` registers (where $i = 0$ and 1).

The SIMCOP modules processing is started using START pulses (green). When the SIMCOP modules are done, they return a DONE pulse (red). Software can choose which accelerators to run for a given step using the [SIMCOP_HWSEQ_STEP_CTRL_i\[7:0\] *_SYNC](#) registers. They do not need to finish at the same time because the hardware sequencer waits for reception of all DONE pulses of used accelerators before moving to the next step.

The hardware sequencer also triggers a series of interrupts that can be used by software. It is possible, for example, for software to change the configuration of inactive sequencing steps. This can be particularly useful to run longer sequences than what is supported by hardware.

For example, software can setup a 4-step long looping sequence: Step 0 → 1 → 2 → 3 → 0 → 1 → When the STEP1_IRQ event is triggered, software can load the configuration to be used next time Step 0 becomes active in the [SIMCOP_HWSEQ_STEP_*_i](#) registers.

9.4.2.3.4.2 Hardware Sequencer Override

By default, the hardware sequencer controls START/DONE pulses of all SIMCOP modules as well as the static controlled crossbar. Software can take the control over some resources by setting the appropriate bits in the [SIMCOP_HWSEQ_OVERRIDE](#) register. Sequencing resources under software control are managed using the [SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE](#) and [SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE](#) registers.

Changes done to the [SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE\[27:11\] *_OFST](#) and [SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE](#) registers have immediate effect. It is the responsibility of software to ensure there is no active traffic on the impacted connection in the static controlled crossbar.

The settings in the [SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE](#) and [SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE](#) registers for resources controlled by the hardware sequencer have no effect.

The SIMCOP DMA START/DONE control is slightly different. Software can trigger one or multiple DMA channels by writing into the [SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE\[7:5\] DMA_TRIGGER](#) bit field. The DMA_TRIGGER bit field returns the written value when all expected DONE pulses have been received from SIMCOP DMA.

Alternatively, SIMCOP modules may be triggered by direct writes into their configuration registers. However, this approach lead to higher initiator load because multiple writes must be done.

9.4.2.4 ISS SIMCOP Hardware Sequencer and Buffers Basic Programming Model

9.4.2.4.1 ISS SIMCOP Hardware Sequencer and Buffers Application Programming Principle

Software must first configure the SIMCOP access tag handling (SIMCOP_DMA_CTRL[7:4] TAG_CNT). Software must ensure there is no active traffic on the SIMCOP master port before changing those registers.

Similarly, software can also preload data like filter coefficient image buffers. This can be handled by the SIMCOP DMA:

- The buffers must first be attached to the SIMCOP DMA using the `SIMCOP_HWSEQ_OVERRIDE` and `SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE` registers.
- Alternatively, software can use the `SIMCOP_HWSEQ_STEP_*_0` registers instead of the override feature. The hardware sequencer ensures that the configuration of Step 0 is applied when the hardware sequencer is disabled.
- Software then configures and starts one or multiple data transfers using the SIMCOP DMA.
- Software monitors SIMCOP DMA events to know when DMA transfers are complete. Other configuration tasks may happen concurrently, but software must ensure that transfers have completed before attaching the memories to another module.

It must then enable the modules going to be used.

Typically, the first and last steps of the macroblock pipeline are different from those in the middle of the pipeline. The hardware sequencer has no specific support for pipe-up and pipe-down. However, software can cut the sequence into smaller ones to still benefit from the hardware sequencing and to avoid software sequencing.

Figure 9-184 shows an example of a 10-step sequence involving two DMA transfers and three modules.

Figure 9-184. Typical Hardware Sequencer Controlled Sequencer With Pipe-Up and Pipe-Down

hwseq-012

The macroblock pipeline is composed of a chain of three accelerators. Data between modules is exchanged using ping-pong buffering.

Pipe-up and pipe-down require four sequencing steps each. The main processing can be done with two steps.

Software configures the hardware sequencer with the four step pipe-up sequence. Each step is executed once. When pipe-up is done, the SIMCOP triggers the `DONE_IRQ` event.

Software then reconfigures the hardware sequencer for the two step main sequence. The number of steps is defined by the amount of data to process. When the main pipe is done, the SIMCOP triggers the `DONE_IRQ` event.

Software finally reconfigures the hardware sequencer with the four step pipe-down sequence. Each step is executed once. When pipe-down is done, the SIMCOP triggers the `DONE_IRQ` event.

Figure 9-185 shows an example of pipe-up and pipe-down.

Figure 9-185. Pipe-Up and Pipe-Down

The hardware sequencer configuration determines which module can access a given SIMCOP memory for a sequence step.

9.4.2.4.2 External CPU Use for Data Processing

An external CPU can be used to perform some data processing as the SIMCOP hardware accelerators do. A similar mechanism to the START/DONE pulse interaction with the SIMCOP hardware accelerators is implemented.

The external CPU receives the request to start processing by the CPU_PROC_START_IRQ interrupt merged at the SIMCOP subsystem level. This interrupt is enabled and acknowledged as usual.

When processing has completed, the CPU generates the DONE pulse to the hardware sequencer by writing 1 into the SIMCOP_HWSEQ_CTRL[10] CPU_PROC_DONE register.

9.4.2.5.2.2 Hardware Sequencer Register Description

Table 9-2646. SIMCOP_HWSEQ_CTRL

Address Offset	0x0000 0068	Instance	HWSEQ
Physical Address	0x4222 0068		
Description	SIMCOP HW sequencer control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HW_SEQ_STEP_COUNTER																BBM_LDC	RESERVED	STEP	CPU_PROC_DONE	BBM_SYNC_CHAN	BBM_STATUS	BITSTREAM	BITSTR_XFER_SIZE	HW_SEQ_STOP	HW_SEQ_START						

Bits	Field Name	Description	Type	Reset
31:16	HW_SEQ_STEP_COUNTER	Number of steps executed by the HW sequencer. HW_SEQ_STEP_COUNTER=0 corresponds to manual sequencing.	RW	0x0
15	BBM_LDC	This bit field is reserved and users should write the reset value to this bit location. Choses if the automatic BBM interface is connected to VLCDJ or LDC (for SCS data). This register shall only be modified when there's no active traffic between VLCDJ/LDC and the BITSTREAM buffer 0x0: VLCDJ 0x1: LCD	RW	0x0
14:13	RESERVED	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
12:11	STEP	This register is automatically updated by the HW sequencer when it is active. Otherwise, SW could use it to activate the content of a given set of step registers (SIMCOP_HWSEQ_STEP_*) or to chose the 1st step number of a sequence.	RW	0x0
10	CPU_PROC_DONE	Used by the CPU to tell that it has completed data processing. This feature should be used together with the CPU_PROC_START_IRQ event Read's always return 0. 0x0: No effect. 0x1: CPU processing completed.	W	0x0
9:8	BBM_SYNC_CHAN	This bit field is reserved and users should write the reset value to this bit location. Defines the SIMCOP DMA HW synchronization channel to be used for BBM. This register is only used when BITSTREAM=ENCODE or DECODE. SW must ensure that the same DMA HW synchronization channel isn't used by the HW sequencer.	RW	0x0
7	BBM_STATUS	This bit field is reserved and users should write the reset value to this bit location. Status of the Bitstream Buffer Management HW. Used only during automatic mode [BITSTREAM=5 or 6] Equals 0 (IDLE) in manual mode [BITSTREAM=0..4]. Set when automatic mode is entered. Automatic encode mode: used to detect when all banks have been flushed after the processing has completed (i.e. but request bank signals have been de-asserted by BBM). Automatic decode mode (BITSTREAM=DECODE): returns to 0 (IDLE) when automatic mode is left (BITSTREAM=COPR). 0x0: BBM is idle 0x1: BBM is busy.	R	0x0

Bits	Field Name	Description	Type	Reset
6:4	BITSTREAM	<p>This bit field is reserved and users should write the reset value to this bit location. BITSTREAM buffer access control</p> <p>0x6: The BITSTREAM buffer is managed by HW as a PING/PONG buffer to support JPEG decode use case. It could be accessed by the SIMCOP DMA or the the VLCDJ module. The BITSTREAM HW sequence is reset when the mode is changed to COPR, VLCDJ or DMA.</p> <p>0x1: Bank 0: DMA (0x1000-0x17FF) Bank 1: DMA (0x1800-0x1FFF)</p> <p>0x0: Bank 0: coprocessor bus (0x1000-0x17FF) Bank 1: coprocessor bus (0x1800-0x1FFF)</p> <p>0x2: Bank 0: VLCDJ.B / LDC (0x000-0x7FF) Bank 1: VLCDJ.B / LDC (0x800-0xFFFF)</p> <p>0x4: Bank 0: VLCDJ.B / LDC (0x000-0x7FF) Bank 1: DMA (0x1800-0x1FFF)</p> <p>0x5: The BITSTREAM buffer is managed by HW as a PING/PONG buffer to support JPEG encode / SCS use case. It could be accessed by the SIMCOP DMA or the the VLCDJ / LDC module. The BITSTREAM HW sequence is reset when the mode is changed to COPR, VLCDJ or DMA. This mode shall not be used when BBM / LDC =1</p> <p>0x3: Bank 0: DMA (0x1000-0x17FF) Bank 1: VLCDJ.B / LDC (0x800-0xFFFF)</p>	RW	0x0
3:2	BITSTR_XFER_SIZE	<p>This bit field is reserved and users should write the reset value to this bit location. Defines the amount of data to be transferred per HW request to the SIMCOP DMA. Bigger sizes lead to better SDRAM efficiency but prevents fine grained DMA transfer arbitration. This register is only used by HW when BITSTREAM=ENCODE or BITSTREAM=DECODE.</p> <p>0x0: 2048 bytes</p> <p>0x1: 1024 bytes</p> <p>0x3: 256 bytes</p> <p>0x2: 512 bytes</p>	RW	0x0
1	HW_SEQ_STOP	<p>Stop the HW sequencer. This feature is typically used to recover from an error condition. Read's always return 0.</p> <p>0x0: No effect.</p> <p>0x1: Stop the HW sequence immediately (dont wait for expected DONE events). Setting this bit while the sequencer is idle has no effect.</p>	W	0x0
0	HW_SEQ_START	<p>Start the HW sequencer. Read's always return 0.</p> <p>0x0: No effect.</p> <p>0x1: Starts step number SIMCOP_HWSEQ_CTRL.STEP of the HW sequence. Setting this bit while the sequencer is running has no effect.</p>	W	0x0

9.4.3 ISS SIMCOP DMA Module

This section describes the direct memory access (DMA) module in the still image coprocessor (SIMCOP) subsystem.

9.4.3.1 ISS SIMCOP DMA Overview

The direct memory access (DMA) module transfers data from system memory to the still image coprocessor (SIMCOP) memories and from SIMCOP memories. [Figure 9-186](#) is an overview of the DMA module in the SIMCOP subsystem.

Figure 9-186. ISS DMA in the SIMCOP Subsystem

The SIMCOP DMA supports the following features:

- Configuration interface, for register access
- Image subsystem (ISS) data interconnect master interface, for system memory access
 - Supports 1-dimensional (1D) and 2-dimensional (2D) burst
- SIMCOP crossbar master interface, for SIMCOP memories access
- Eight logical channels supported
- Hardware synchronization support
- 2-dimensional (2D) addressing transfers

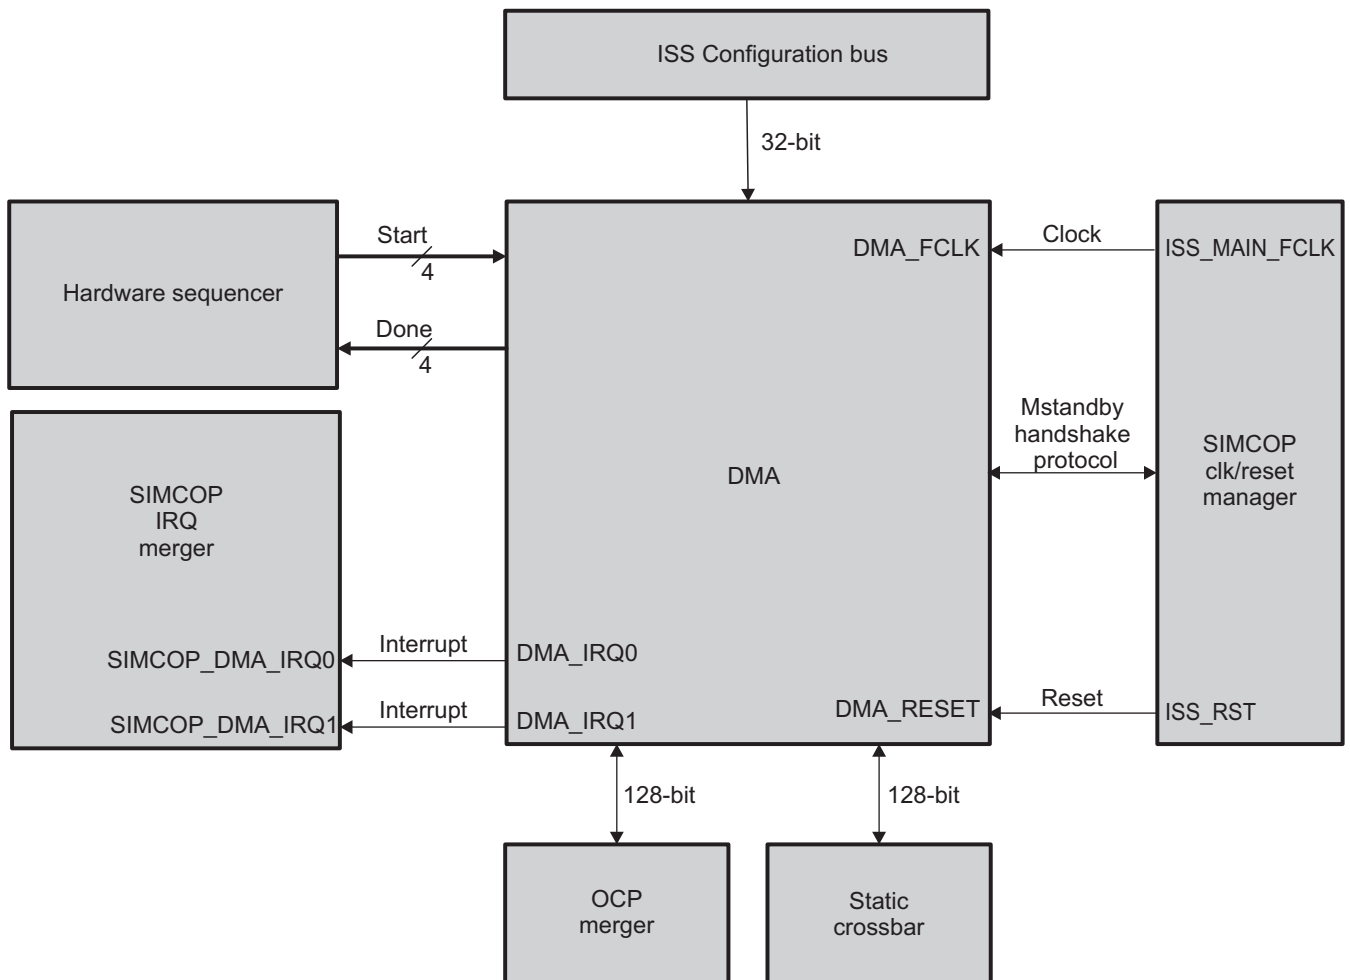

- 2D data block transfer (base address, stride, height, width)
- Array of 2D block transfer support
- Performance: Software-controllable bandwidth limiter

The SIMCOP DMA is not a general-purpose DMA. It can perform only 16-byte aligned transfers and does not have access to the ISS configuration interconnect. SDMA must be used instead.

9.4.3.2 ISS SIMCOP DMA Integration

The DMA module is part of the SIMCOP subsystem in the ISS. Figure 9-187 shows the integration of the DMA in the SIMCOP subsystem.

Figure 9-187. DMA Engine Integration

9.4.3.3 ISS SIMCOP DMA Functional Description

9.4.3.3.1 ISS SIMCOP DMA Block Diagram

Figure 9-188 is a block diagram of the SIMCOP DMA.

Figure 9-188. ISS SIMCOP DMA Block Diagram

An external initiator sets up logical channels using the configuration interface.

When a logical channel becomes active, a transfer must be executed. A transfer corresponds to a 2D block of data copied from system memory to SIMCOP memory and vice versa.

A transfer is decomposed into one or multiple transactions by the transaction generation unit.

The scheduler issues transactions when tags are available. There can be one outstanding command per tag on the ISS data interconnect.

9.4.3.3.2 ISS SIMCOP DMA Power Management

Table 9-2670 lists the power-management features available in the DMA module.

Table 9-2670. Local Power-Management Features

Feature	Registers	Description
Master standby modes	SIMCOP_DMA_SYSCONFIG [5:4] STANDBYMODE	Force-standby, no-standby, and smart-standby modes are available.

9.4.3.3.3 ISS SIMCOP DMA Interrupt Requests

The SIMCOP DMA module can generate two interrupts, SIMCOP_DMA_IRQ0 and SIMCOP_DMA_IRQ1. These two interrupts are controlled by four registers:

- [SIMCOP_DMA_IRQSTATUS_RAW_j](#): The status of the interrupt before masking
- [SIMCOP_DMA_IRQSTATUS_j](#): The status of the interrupt after masking
- [SIMCOP_DMA_IRQENABLE_SET_j](#): Enable an interrupt to propagate to SIMCOP_DMA_IRQi signal (unmask)
- [SIMCOP_DMA_IRQENABLE_CLR_j](#): Disable an interrupt to propagate to SIMCOP_DMA_IRQi signal (mask)

To clear an interrupt, software must write 1 in the corresponding bit of the [SIMCOP_DMA_IRQSTATUS_j](#) register even if the event is not enabled ([SIMCOP_DMA_IRQSTATUS_RAW_j](#) is also cleared).

[Table 9-2671](#) list all the SIMCOP DMA events that can lead to an interrupt generation.

Table 9-2671. ISS SIMCOP DMA Events List

Bit Name	Bit	Event
BUS_ERR	0	Error occurred on bus
CHAN0_BLOCK_DONE_IRQ	16	Channel 0 has completed transfer of one 2D block.
CHAN1_BLOCK_DONE_IRQ	17	Channel 1 has completed transfer of one 2D block.
CHAN2_BLOCK_DONE_IRQ	18	Channel 2 has completed transfer of one 2D block.
CHAN3_BLOCK_DONE_IRQ	19	Channel 3 has completed transfer of one 2D block.
CHAN4_BLOCK_DONE_IRQ	20	Channel 4 has completed transfer of one 2D block.
CHAN5_BLOCK_DONE_IRQ	21	Channel 5 has completed transfer of one 2D block.
CHAN6_BLOCK_DONE_IRQ	22	Channel 6 has completed transfer of one 2D block.
CHAN7_BLOCK_DONE_IRQ	23	Channel 7 has completed transfer of one 2D block.
CHAN0_FRAME_DONE_IRQ	24	Channel 0 has completed transfer of the full frame.
CHAN1_FRAME_DONE_IRQ	25	Channel 1 has completed transfer of the full frame.
CHAN2_FRAME_DONE_IRQ	26	Channel 2 has completed transfer of the full frame.
CHAN3_FRAME_DONE_IRQ	27	Channel 3 has completed transfer of the full frame.
CHAN4_FRAME_DONE_IRQ	28	Channel 4 has completed transfer of the full frame.
CHAN5_FRAME_DONE_IRQ	29	Channel 5 has completed transfer of the full frame.
CHAN6_FRAME_DONE_IRQ	30	Channel 6 has completed transfer of the full frame.
CHAN7_FRAME_DONE_IRQ	31	Channel 7 has completed transfer of the full frame.

9.4.3.3.4 ISS SIMCOP DMA Logical Channels

In the context of the SIMCOP, multiple logical channels are required to offload the external initiator. Typical uses of multiple contexts are:

- Run a read transfer followed by a write transfer. When this transfer is complete, new input data is fetched from system memory and stored in the image buffers.
- Read or write YUV4:2:0 data from system memory; YUV4:2:0 data is stored in two different system memory buffers.

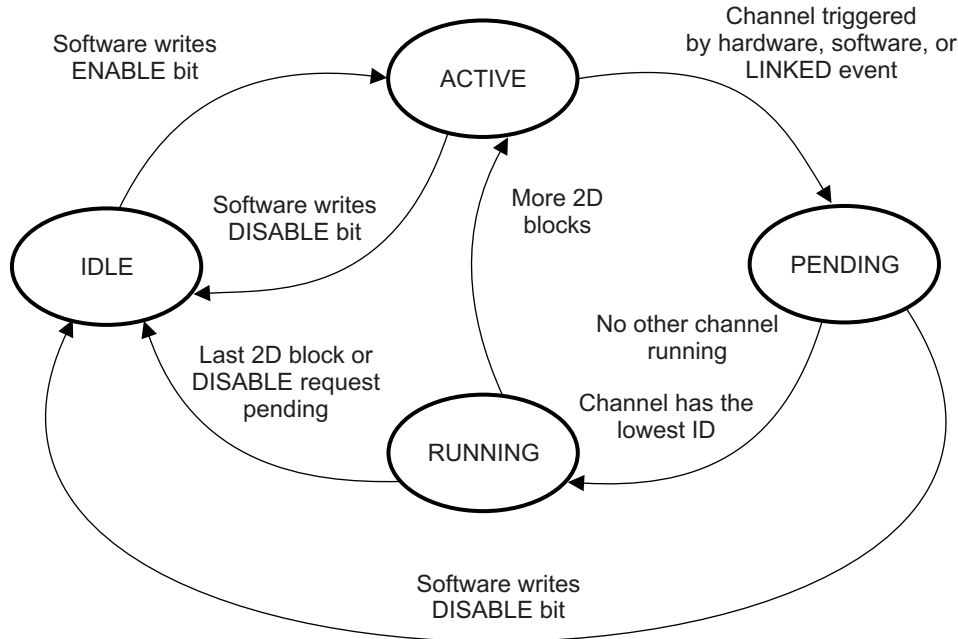

9.4.3.3.4.1 Logical Channel States

The SIMCOP DMA supports up to eight (([SIMCOP_DMA_HWINFO](#)[2] CHAN+1) × 4) logical channels. Each logical channel can be configured and triggered separately.

Idle logical channels must be configured and enabled ([SIMCOP_DMA_CHAN_CTRL_i](#)[0] ENABLE = 1) to be used.

[Figure 9-189](#) shows the different states of a logical channel. Software can poll the current state from the [SIMCOP_DMA_CHAN_CTRL_i](#)[4:3] STATUS bit field.

Figure 9-189. DMA Logical Channel States

scpdma-003

When a trigger event is received by a channel in the ACTIVE state, it moves to the PENDING state. Trigger events received when the channel is in the IDLE, PENDING, or RUNNING state are discarded.

A logical channel is automatically disabled by hardware when a complete frame (all 2D blocks) is transferred. It can be disabled earlier by software by writing the `SIMCOP_DMA_CHAN_CTRL_i[1]` DISABLE bit. When a disable request occurs in the RUNNING state, it is memorized and executed when the channel leaves the RUNNING state. Pending disable requests have higher priority than channel trigger events.

When multiple logical channels are pending simultaneously, the following rules apply:

- An ongoing transfer of a 2D block is never stopped. It must complete before the next one starts.
- The logical channel with the lowest ID wins the arbitration (that is, CHAN0 has higher priority than CHAN1). Software can give higher priority to a channel by choosing a lower ID.

This situation can, for example, occur when software triggers a channel while a transfer is ongoing for another one. Two types of interrupts can be generated:

- `CHANx_BLOCK_DONE_IRQ` (where x = channel number): It is generated when the channel leaves the RUNNING state (RUNNING -> ACTIVE or RUNNING -> IDLE).
- `CHANx_FRAME_DONE_IRQ` (where x = channel number): It is generated when the channel enters the IDLE state.

9.4.3.3.4.2 Logical Channel Chaining, Trigger, and Hardware Synchronization

Active logical channels can be triggered:

- By software. Writes the `SIMCOP_DMA_CHAN_CTRL_i[2]` SWTRIGGER bit
- By a hardware DMA request. A channel can be made sensitive to a pulse on the `START[y]` input when `SIMCOP_DMA_CHAN_CTRL_i[19:17]` HWSTART = y has been configured by software.
- When the previous channel in the linked list finishes. This feature is enabled through the `SIMCOP_DMA_CHAN_CTRL_i[16:12]` LINKED bit field of the preceding channel in the chain.

When a channel completes, it can optionally send a pulse to the `DONE[y]` output. Software enables this feature by configuring `SIMCOP_DMA_CHAN_CTRL_i[22:20]` HWDONE = y.

Typically, the START + DONE synchronization mechanism is used together with the SIMCOP hardware sequencer. The hardware sequencer sends a pulse to START[y] a data transfer and the SIMCOP DMA responds with a DONE[y] pulse when the transfer completes. A transfer can be composed of one or multiple logical channels. For example, a YUV4:2:0-NV12 block copy from system memory to SIMCOP local memories requires two chained logical channels.

CAUTION

Software must ensure that only one trigger event source is selected at a given time for a logical channel; otherwise, unpredictable behavior may occur.

Typically, the following combinations can be used:

- Single channel triggered by software: Hardware synchronization and linking are disabled. Software writes the `SIMCOP_DMA_CHAN_CTRL_i[2]` SWTRIGGER bit to start the transfer of one 2D block. Software must not trigger the channel again before the `CHANx_BLOCK_DONE_IRQ` (where x = channel number) event is generated by the DMA.
- Channels chain-triggered by software: Multiple channels are linked together using the `SIMCOP_DMA_CHAN_CTRL_i[16:12]` LINKED bit field. Software triggers the first one in the chain and monitors the `CHANx_BLOCK_DONE_IRQ` (where x = channel number) event to know when the chain can be triggered again.
- Single channel triggered by hardware synchronization: Sensitivity on START pulses is activated through the `SIMCOP_DMA_CHAN_CTRL_i[19:17]` HWSTART bit field. DONE pulse generation is activated using the `SIMCOP_DMA_CHAN_CTRL_i[22:20]` HWSTOP bit field.
- Channels chain-triggered by hardware: Multiple channels are linked together using the `SIMCOP_DMA_CHAN_CTRL_i[16:12]` LINKED bit field. Sensitivity on START pulses is activated for the first channel in the chain through the `SIMCOP_DMA_CHAN_CTRL_i[19:17]` HWSTART bit field. DONE pulse generation for the last channel in the chain is activated using the `SIMCOP_DMA_CHAN_CTRL_i[22:20]` HWDONE bit field.

9.4.3.3.4.3 Logical Channel Data Transfer

Each logical channel can handle 4D transfers from system memory to SIMCOP memory and vice versa.

A frame is composed of `SIMCOP_DMA_CHAN_FRAME_i[9:0]` XCNT * `SIMCOP_DMA_CHAN_FRAME_i[25:16]` YCNT 2D blocks of data. A single 2D block of data is transferred each time a logical channel is in the RUNNING state.

The size of a 2D block is `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4]` XNUM * `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16]` YNUM words of 128 bits. The SIMCOP DMA can transfer only full 128-bit words.

2D blocks may overlap in system memory. This feature is typically used for source data fetches from system memory to handle filter dependencies. If this feature is not used, software must set:

- `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4]` XNUM = `SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4]` XSTEP
- `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16]` YNUM = `SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16]` YSTEP

Figure 9-190 shows DMA addressing.

Figure 9-190. DMA Addressing

scpdma-014

The base position of 2D blocks in system memory is automatically computed by the SIMCOP DMA. The base address is computed using the following formula:

$$\text{SMEM_BASE} = \text{SIMCOP_DMA_CHAN_SMEM_ADDR_i}[31:4] \text{ ADDR} + \text{Bx} \times \text{SIMCOP_DMA_CHAN_BLOCK_STEP_i}[14:4] \text{ XSTEP} + \text{By} \times \text{SIMCOP_DMA_CHAN_BLOCK_STEP_i}[29:16] \text{ YSTEP} \times \text{SIMCOP_DMA_CHAN_SMEM_OFST_i}[19:4] \text{ OFST}$$

All 2D blocks of a logical channel have the same location in SIMCOP local memories:

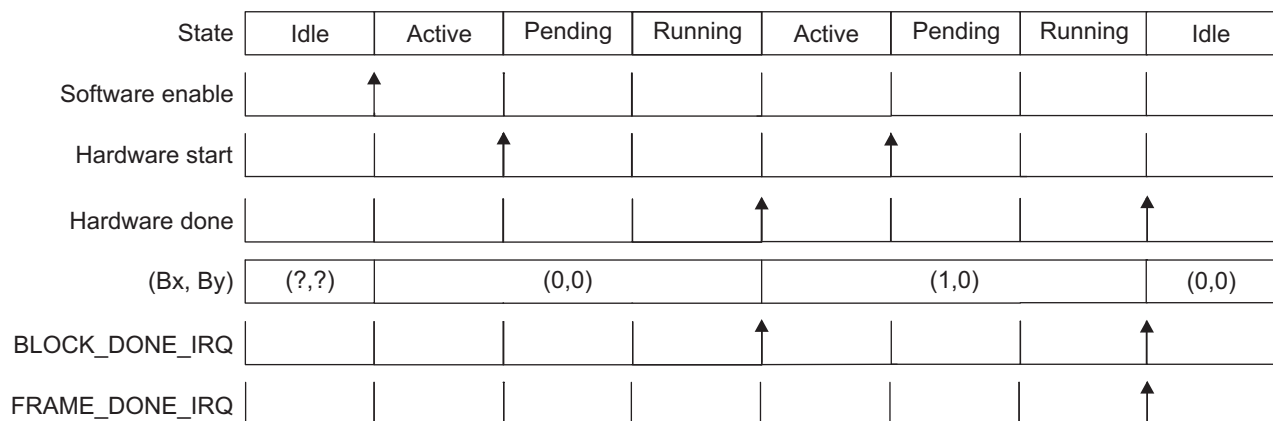

$$\text{BUF_BASE} = \text{SIMCOP_DMA_CHAN_BUF_ADDR_i}[23:4] \text{ ADDR}$$

The same functionality can also be used to read or write sparse data from SDRAM.

Software can poll the status of a channel using the `SIMCOP_DMA_CHAN_CURRENT_BLOCK_i` register. It holds the Bx, By values of the last-transferred 2D block. The Bx, By values are reset when a channel is enabled (set the `SIMCOP_DMA_CHAN_CTRL_i[0]` ENABLE bit) and they are updated when a channel enters the RUNNING state.

Figure 9-191 shows an example of a 2-block large transfer.

Figure 9-191. 2-Block Large Transfer Example

scpdma-005

9.4.3.3.5 Transaction Generation

Each transfer is decomposed into one or multiple transactions by the DMA engine. The firmware can define:

- Burst generation for regular or tiled accesses ([SIMCOP_DMA_CHAN_CTRL_j\[6\] TILERMODE](#)). Additional parameters must be defined for tiled accesses. See , *Block Bursts for Tiled Transfers*.
- The maximum burst size ([SIMCOP_DMA_CTRL\[1:0\] MAX_BURST_SIZE](#)). It must be aligned with the interconnect configuration.
- Use of posted or nonposted writes ([SIMCOP_DMA_CTRL\[3\] POSTED_WRITES](#)). It must be aligned with the interconnect configuration. Mainly, in a multichannel system memory, system bursts must be issued nonposted.

9.4.3.3.5.1 Incrementing Bursts for Regular Transfers

Lines of 2D blocks are processed sequentially. The following transaction process is used for a given line:

1. Perform a single nonaligned burst from the start address to the next [SIMCOP_DMA_CTRL\[1:0\] MAX_BURST_SIZE](#) boundary (or less if the transfer is smaller).
2. Perform "n" aligned bursts (n can be 0).
3. Perform a single nonaligned burst up to the end address (if needed).

A transaction is aligned when the start address modulo burst length is 0.

9.4.3.4 ISS SIMCOP DMA Basic Programming Model

9.4.3.4.1 Initialization of Surrounding Modules

To initialize the DMA, the surrounding modules must be initialized. [Table 9-2672](#) lists these modules.

Table 9-2672. Initialization of Surrounding Modules

Module	Minimum Required Setting	Optional Settings
CLKC	Enable SIMCOP clock	
Buffers	Configure DMA access to image buffer	
SIMCOP CTRL		Configure SIMCOP CTRL to handle DMA interrupts

9.4.3.4.2 ISS SIMCOP DMA Channel Configuration and Hardware Synchronization

Software must fully configure a DMA channel before enabling it. It then configures channel linking and the used synchronization method.

The following example shows four logical channels chained with hardware synchronization used to copy YUV4:2:0-NV12 data from SIMCOP local memories to system memory, and then to copy YUV4:2:0-NV12 data from system memory to SIMCOP local memories.

YUV4:2:0-NV12 data is stored in two separate buffers in SDRAM. Therefore, two channels are used for the SIMCOP -> system copy, and two channels are used for the system -> SIMCOP copy.

In this example, the intent is to transfer a 2 x 2 array of 64 x 32 pixel blocks. It is assumed that input data is stored contiguously in system memory and that the output buffer size in system memory is 256 x 32 pixels. In SIMCOP local memories, data is contiguously stored starting at address 0

The following configuration is used:

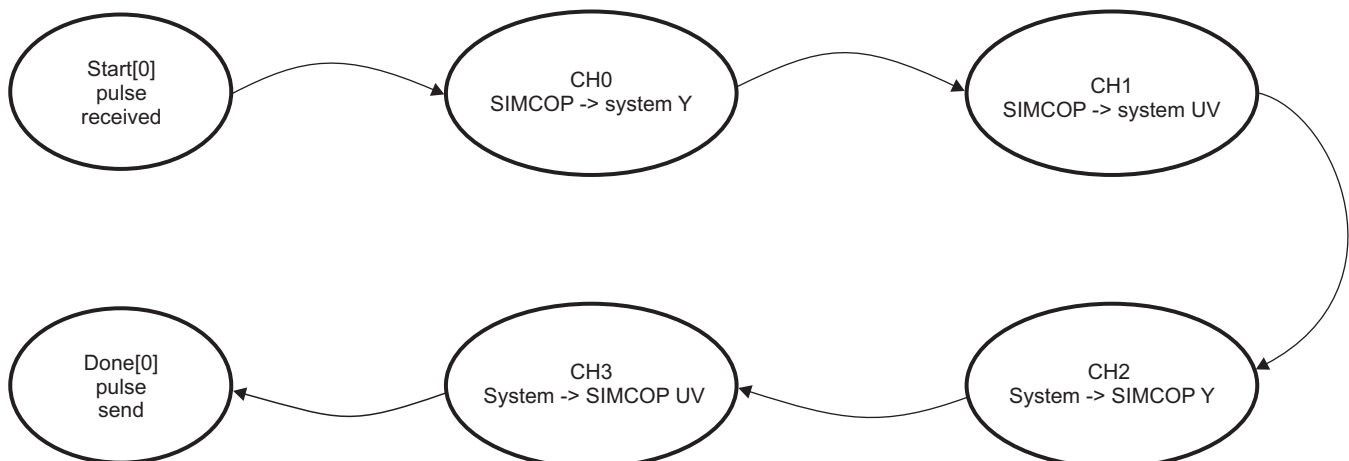

- Channel $i = 0$, input Y buffer:
 - `SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4]` ADDR = Start address of Y input buffer
 - `SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4]` OFST = 16 (= 256 bytes)
 - `SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4]` ADDR = 0
 - `SIMCOP_DMA_CHAN_BUF_OFST_i[23:4]` OFST = 8 (= 128 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4]` XNUM = 4 (= 64 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16]` YNUM = 32
 - `SIMCOP_DMA_CHAN_FRAME_i[9:0]` XCNT = 2
 - `SIMCOP_DMA_CHAN_FRAME_i[25:16]` YCNT = 2
 - `SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4]` XSTEP = 4 (= 64 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16]` YSTEP = 32
- Channel $i = 1$, input UV buffer:
 - `SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4]` ADDR = Start address of UV input buffer
 - `SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4]` OFST = 16 (= 256 bytes)
 - `SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4]` ADDR = 128 (2 KiB)
 - `SIMCOP_DMA_CHAN_BUF_OFST_i[23:4]` OFST = 8 (= 128 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4]` XNUM = 4 (= 64 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16]` YNUM = 16
 - `SIMCOP_DMA_CHAN_FRAME_i[9:0]` XCNT = 2
 - `SIMCOP_DMA_CHAN_FRAME_i[25:16]` YCNT = 2
 - `SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4]` XSTEP = 4 (= 64 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16]` YSTEP = 16
- Channel $i = 2$, output Y buffer:

- `SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4]` ADDR = Start address of Y output buffer
- `SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4]` OFST = 16 (= 256 bytes)
- `SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4]` ADDR = 0
- `SIMCOP_DMA_CHAN_BUF_OFST_i[23:4]` OFST = 8 (= 128 bytes)
- `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4]` XNUM = 4 (= 64 bytes)
- `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16]` YNUM = 32
- `SIMCOP_DMA_CHAN_FRAME_i[9:0]` XCNT = 2
- `SIMCOP_DMA_CHAN_FRAME_i[25:16]` YCNT = 2
- `SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4]` XSTEP = 4 (= 64 bytes)
- `SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16]` YSTEP = 32
- Channel $i = 3$, output UV buffer
 - `SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4]` ADDR = Start address of UV output buffer
 - `SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4]` OFST = 16 (= 256 bytes)
 - `SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4]` ADDR = 128 (= 2 KiB)
 - `SIMCOP_DMA_CHAN_BUF_OFST_i[23:4]` OFST = 8 (= 128 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4]` XNUM = 4 (= 64 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16]` YNUM = 16
 - `SIMCOP_DMA_CHAN_FRAME_i[9:0]` XCNT = 2
 - `SIMCOP_DMA_CHAN_FRAME_i[25:16]` YCNT = 2
 - `SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4]` XSTEP = 4 (= 64 bytes)
 - `SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16]` YSTEP = 16

Figure 9-192 shows the channel linking chain used. All four channels are executed sequentially. Doing so prevents access collision in SIMCOP local memories or system memories. Channel 0 is started by a `START[0]` pulse from SIMCOP. When Channel 3 completes the last transfer, a pulse to `DONE[0]` is sent back to SIMCOP.

Figure 9-193 shows the temporal channel sequence.

Figure 9-192. YUV4:2:0-NV12 Read/Write Chain

scpdma-006

Figure 9-193. Temporal Channel Sequence

The following configuration is used for each channel:

- Channel $i = 0$, input Y buffer, first in sequence:
 - `SIMCOP_DMA_CHAN_CTRL_i[16:12]` LINKED = 0x11 (= CHAN 1)
 - `SIMCOP_DMA_CHAN_CTRL_i[19:17]` HWSTART = 0x4 (= CHAN 0)
 - `SIMCOP_DMA_CHAN_CTRL_i[5]` DIR = 1 (= SIMCOP buffers -> system memory)
 - `SIMCOP_DMA_CHAN_CTRL_i[0]` ENABLE = 1
- Channel $i = 1$, input UV buffer, second in sequence:
 - `SIMCOP_DMA_CHAN_CTRL_i[16:12]` LINKED = 0x12 (= CHAN 2)
 - `SIMCOP_DMA_CHAN_CTRL_i[5]` DIR = 1 (= SIMCOP buffers -> system memory)
 - `SIMCOP_DMA_CHAN_CTRL_i[0]` ENABLE = 1
- Channel $i = 2$, output Y buffer, third in sequence:
 - `SIMCOP_DMA_CHAN_CTRL_i[16:12]` LINKED = 0x13 (= CHAN 3)
 - `SIMCOP_DMA_CHAN_CTRL_i[5]` DIR = 0 (= system memory -> SIMCOP buffers)
 - `SIMCOP_DMA_CHAN_CTRL_i[0]` ENABLE = 1
- Channel $i = 3$, output UV buffer, last in sequence:
 - `SIMCOP_DMA_CHAN_CTRL_i[16:12]` LINKED = CHAN 1
 - `SIMCOP_DMA_CHAN_CTRL_i[22:20]` HWSTOP = 0x4 (= CHAN 0)
 - `SIMCOP_DMA_CHAN_CTRL_i[5]` DIR = 0 (= system memory -> SIMCOP buffers)
 - `SIMCOP_DMA_CHAN_CTRL_i[0]` ENABLE = 1

Software can read the status of a logical channel at any time. However, logical channel configuration registers can be changed only when the channel is in the IDLE state.

Software can disable a logical channel by writing the `SIMCOP_DMA_CHAN_CTRL_i[1]` DISABLE bit. A channel is effectively disabled when `SIMCOP_DMA_CHAN_CTRL_i[4:3]` STATUS = IDLE. In case of linked channels, software must disable all channels in the chain and wait until all of them are back in the IDLE state before channels can be reprogrammed.

9.4.3.4.3 Software Synchronization

Software performs the following sequence:

1. Configures the channel
2. Enables the channel
3. Triggers the channel by writing the [SIMCOP_DMA_CHAN_CTRL_i\[2\]](#) SWTRIGGER bit
4. Waits for BLOCK_DONE_IRQ

Step 2 and Step 4 are repeated until all 2D blocks have been transferred.

9.4.4 ISS SIMCOP VTNF Module

This section describes the Temporal Video Noise Filter (VTNF) module in the still image coprocessor (SIMCOP) subsystem.

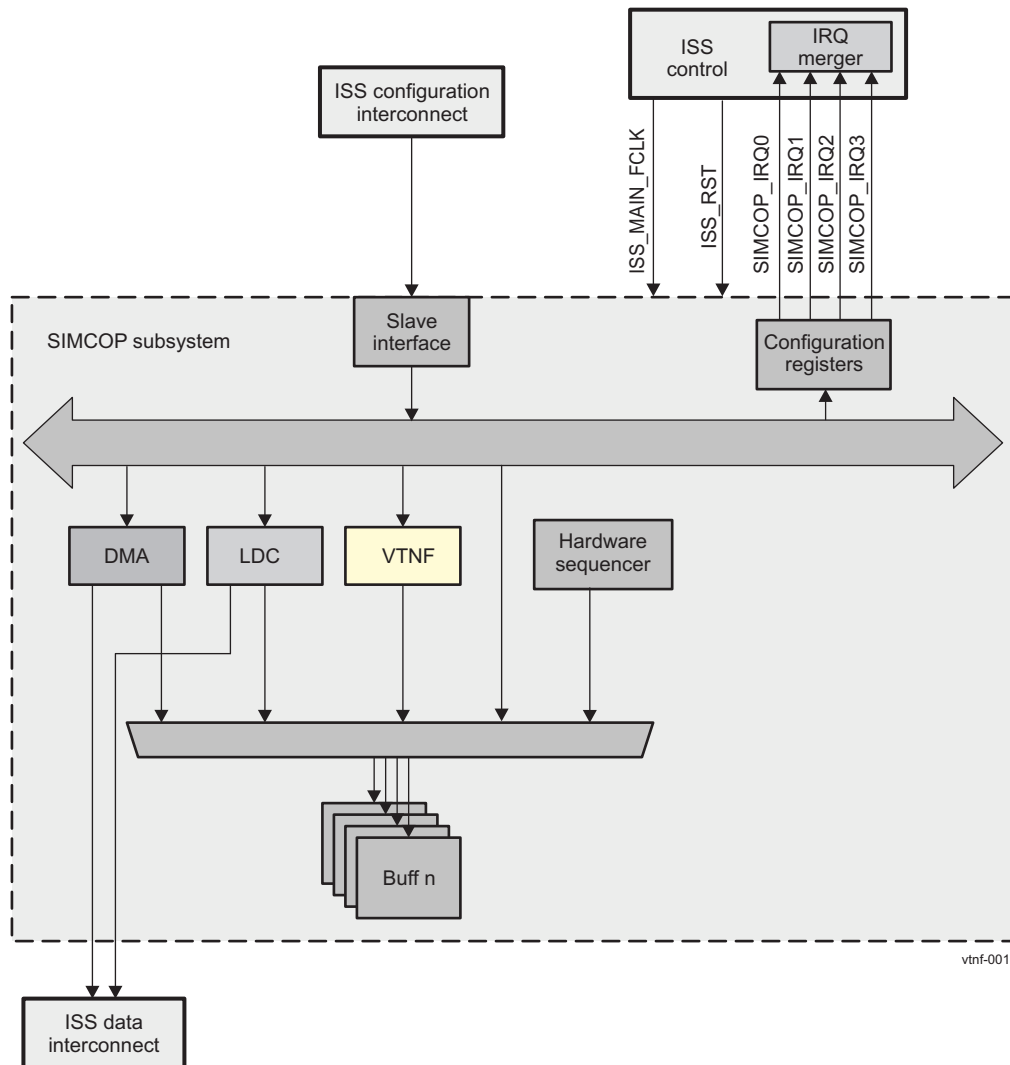

9.4.4.1 ISS SIMCOP VTNF Overview

The VTNF module implements temporal filtering to improve visual quality and video compression efficiency of typical video source sequences.

The module works in YUV420 NV12, NV21 and YV12 formats, accepts a current frame input, previous frame input, and generates a filtered current frame output.

The module is one of the coprocessors inside SIMCOP subsystem, relying on SIMCOP DMA to read/write blocks of current frame input/output and previous frame output, and using shared memory to exchange data with DMA and other coprocessors. Figure 9-194 is an overview of the VTNF module in the SIMCOP subsystem.

Figure 9-194. ISS SIMCOP VTNF in the SIMCOP Subsystem

The VTNF supports the following features:

- YUV420 data format, following NV12, NV21 and YV12 formats
- Programmable multiple-of-16 block width for NV12/NV21, and multiple-of-32 block width for YV12
- Programmable multiple-of-4 block height

- Block data aligned to 128-bit local memory words
- Programmable IIR filtering coefficients (blending factor in lookup tables)
- Flexibility in input/output memory allocation (1/2/4 image buffers)
- Performance up to 700 Mpix/sec

The VTNF does not support:

- YUV422 or Bayer data format
- Luma-only or chroma-only operation
- Misaligned data blocks for previous frame
- Misaligned data blocks for current frame input
- Misaligned data blocks for current frame output

9.4.4.2 ISS SIMCOP VTNF Environment

VTNF is typically used in video record use cases, after ISP (image signal processing) and right before video codec. As the system reduces memory/external SDRAM traffic, it executes a few processing steps that are compatible in dependency, block dimension, etc, in one memory pass. The [Figure 9-195](#) diagram shows VTNF chaining through image buffers (IM).

vtnf-002

VTNF has one slave interface for programming the config registers. It has 32-bit data bus, and operates at half the frequency of functional clock. VTNF has an 128-bit memory bus for connecting to the image buffers. It issues one 128-bit memory request per cycle, and the memory bus interface can connect to multiple image buffers via decoding logic at the SIMCOP level.

VTNF connects up to 4 image buffers (4KB) each at a time, with 128-bit wide data bus. Address range = $4 \times 4KB / 128\text{-bit} = 4 \times 4KB / 16B = 1K$, therefore address width = 10 bits.

9.4.4.2.1 ISS SIMCOP VTNF Protocols and Data Formats

VTNF input YUV420 data complies to the NV12 or NV21 format

VTNF output YUV420 data can be either NV12 or NV21 or YV12. For YV12 format output, input should be NV12

U and V processing is symmetrical, so current frame input, previous frame input, and current frame output should be either all NV12, or all NV21, and not mix between the two.

All combinations of YUV420 formats and whether each is supported is shown in the [Table 9-2711](#)

Table 9-2711. ISS SIMCOP VTNF color format support matrix

		Previous frame output = current frame output		
		NV12	NV21	YV12
Current frame input	NV12	x		x
	NV21		x	
	YV12			

YUV420 NV12 data format has the luma (Y) of one entire frame stored together, and the chroma components (U and V) interleaved pixel-by-pixel, and stored separately. NV21 is the same, except with U and V exchanged in the interleaving order.

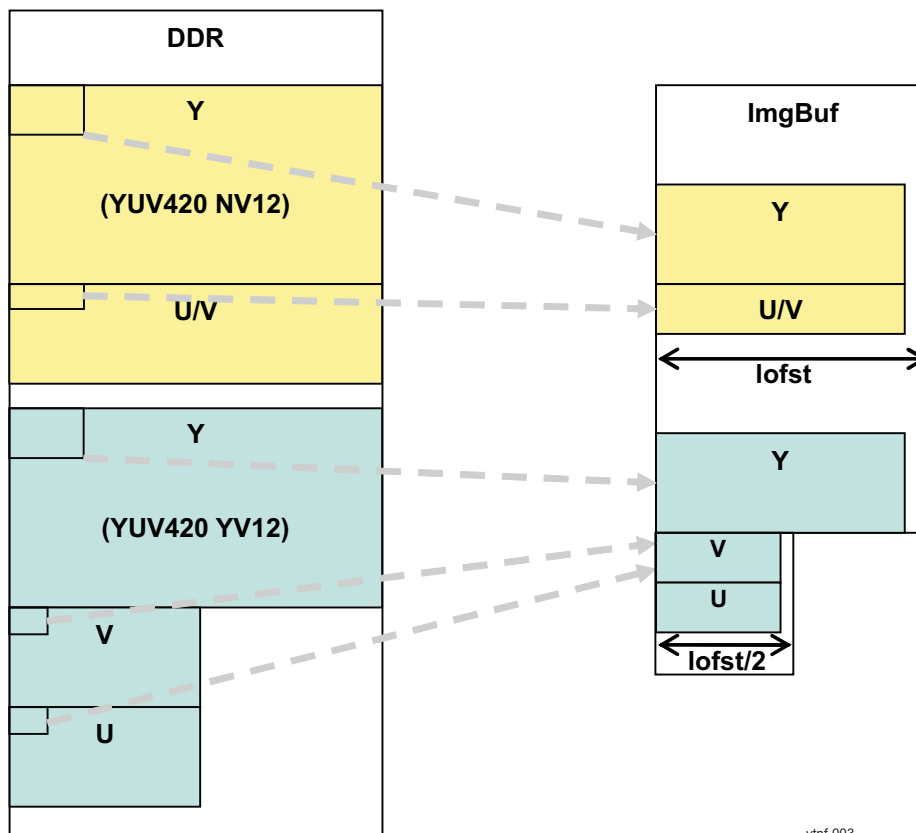

YUV420 YV12 data format has the luma (Y) of one entire frame stored together, followed by the V component for entire frame (half width and half height Y), then followed by the U component for entire frame (same size as V).

As VTNF processes one block at a time, each pointer (current frame input/output, previous frame output) points to Y for one block, followed by the U/V data, interleaved for NV12/NV21, separate arrays for YV12.

The line offset parameter [VTNF_LOFST](#)[15:4] LOFST is used for line offset for luma array and for NV12/NV21 interleaved UV array, and can be any multiple of 16 greater than or equal to block width.

For the YV12 separate U and V arrays, as the data width is half of luma array, line offset of LOFST/2 is used. In this case, LOFST must be a multiple of 32, to avoid straddling 128-bit memory words. Block width is also a multiple of 32.

Figure 9-196. VTNF YUV420 NV12/NV21 and YV12 data formats

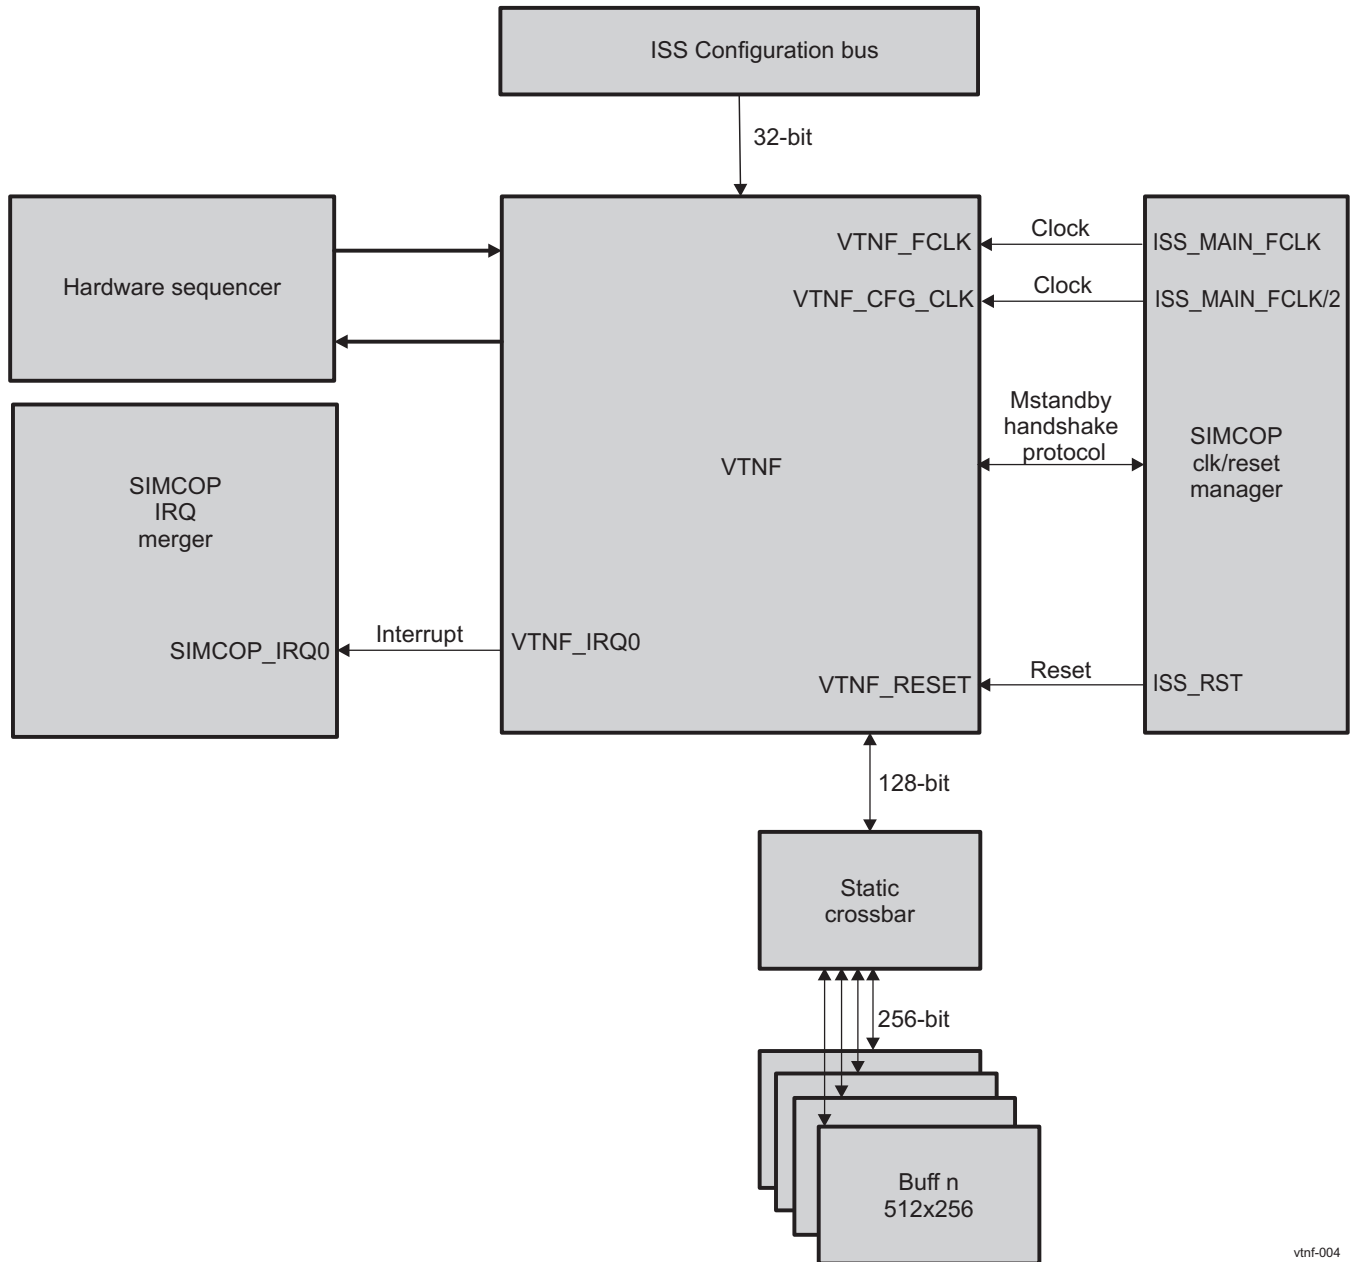

vtnf-003

9.4.4.3 ISS SIMCOP VTNF Integration

The VTNF module is part of the SIMCOP subsystem in the ISS. Figure 9-197 shows the integration of the VTNF in the SIMCOP subsystem.

Figure 9-197. VTNF Engine Integration

vtnf-004

Table 9-2712. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
VTNF	PD_EVE3	L3_MAIN via ISS interconnect

Table 9-2713. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
VTNF	VTNF_FCLK	ISS_MAIN_FCLK	ISS	Functional clock. It is used by all ISS sub-modules and ISS top level resources.
	VTNF_CFG_CLK	ISS_MAIN_FCLK / 2	SIMCOP TOP	Synchronous configuration clock running at half the speed of the functional clock.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
VTNF	VTNF_RST	ISS_RST	ISS	ISS and SIMCOP global reset

For information about clock and reset management, see [Section 9.4.1.2.1](#), *ISS SIMCOP Local Power and Clock Management*.

Table 9-2714. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
VTNF	VTNF_IRQ0	SIMCOP_IRQ0	SIMCOP IRQ merger	Interrupt triggered by SIMCOP VTNF. It indicates that one block of VTNF task has been completed. It is synchronous to the config clock and active for one config clock cycle.

For more information about interrupt requests, see [Section 9.4.1.2.3](#), *Interrupt Merger*.

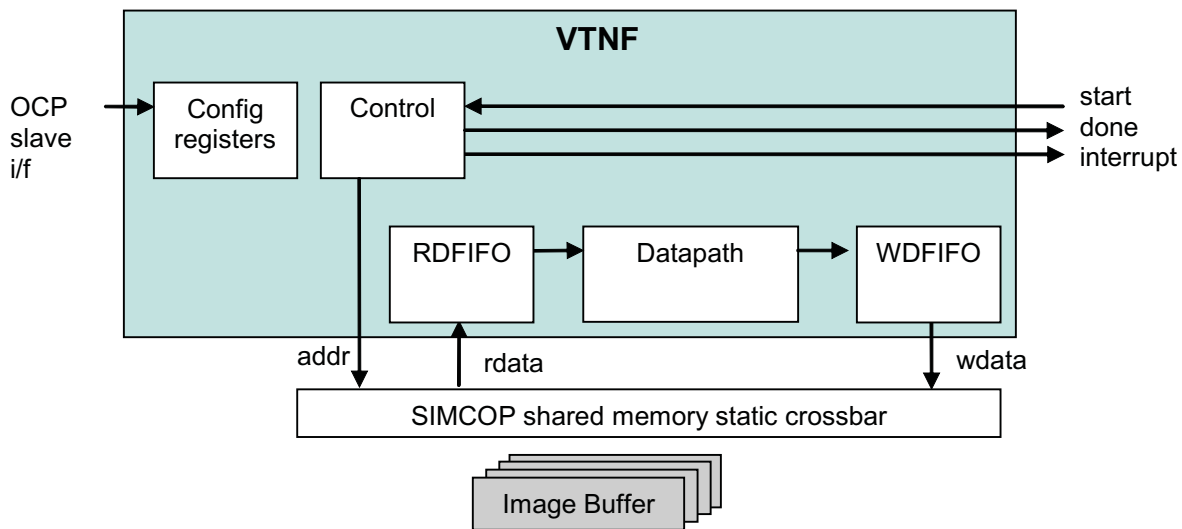

NOTE: VTNF does not generate any DMA request, though VTNF_IRQ0 done signal to the SIMCOP HW sequencer is often used to trigger DMA.

9.4.4.4 ISS SIMCOP VTNF Functional Description

9.4.4.4.1 ISS SIMCOP VTNF Block Diagram

Figure 9-198 is a block diagram of the SIMCOP VTNF.

Figure 9-198. ISS SIMCOP VTNF Block Diagram

vtnf-005

VTNF module consists of:

- Config registers, for module enable (start a block), module status, block dimension, and other parameters.
- Control: controls block level interaction (start/done) and generate memory read/write and address.
- RDFIFO: read data FIFO, holds read data from the SIMCOP shared memory interface, and delivers it to datapath.
- Datapath: algorithm implementation logic, pulls data from RDFIFO, compute output, and pushes output to WDFIFO.
- WDFIFO: write data FIFO, holds outcome data from datapath, and delivers to the SIMCOP shared memory interface

NOTE: There is just one memory transaction per cycle, to allow for minimal resources in SIMCOP, but it is feasible to connects to multiple image buffers to allow bigger block size.

9.4.4.4.2 ISS SIMCOP VTNF Clocks Management

Table 9-2715 lists the clocks-management features available in the VTNF module.

Table 9-2715. VTNF Clocks-Management Features

Feature	Registers	Description
Autogating clocks	VTNF_CTRL [10] STANDBYMODE	Internal clock gating on interface and functional clock 0 = clocks are free-running 1 = clocks are gated off in subblocks that are not needed for operation

9.4.4.4.3 ISS SIMCOP VTNF Interrupt Requests

The SIMCOP VTNF module can generate one interrupt, VTNF_IRQ0. It is a task completion interrupt when it completes a task. It is synchronous to the config clock and active for one config clock cycle. This interrupt is controlled by the [VTNF_CTRL\[8\] INTEN](#)

9.4.4.4.4 ISS SIMCOP VTNF Configuration

9.4.4.4.4.1 ISS SIMCOP VTNF Initialization

The following parameters should be programmed before starting VTNF task:

- Trigger source [VTNF_CTRL\[9\] TRIG_SRC](#): either from config register write or HW sequencer sending pulse on VTNF_start signal
- Data format [VTNF_CFG\[0\] FMT](#): 0 for YUV420-NV12/NV21, 1 for YUV420-YV12
- Block width [VTNF_SZ\[15:0\] BLKW](#): must be multiple of 16 for NV12/NV21, and multiple of 32 for YV12, up to 512
- Block height [VTNF_SZ\[31:16\] BLKH](#): must be a multiple of 4 and up to 128
- Current input frame byte address in image buffer [VTNF_CADR\[15:4\] ADDR](#): 128-bit aligned or multiple of 16
- Previous output frame byte address in image buffer [VTNF_PADR\[15:4\] ADDR](#): 128-bit aligned or multiple of 16
- Output frame byte address in image buffer [VTNF_OADR\[15:4\] ADDR](#): 128-bit aligned or multiple of 16
- Line offset [VTNF_LOFST\[15:4\] LOFST](#): must be multiple of 16 for NV12/NV21, and multiple of 32 for YV12
- [VTNF_LOFST\[15:4\] LOFST](#) >= [VTNF_SZ\[15:0\] BLKW](#)
- Color weights [VTNF_WEIGHTS\[5:0\] W1](#), [VTNF_WEIGHTS\[21:16\] W2](#), each 0~63, one byte of space per weight
- Rounding bit count before lookup, [VTNF_CFG\[7:4\]T](#) = 0~15
- Lookup tables [VTNF_LUT1\[0..31\]](#), [VTNF_LUT2\[0..31\]](#), each entry 0~255, one byte of space per entry

After the parameters are configured, computation can be started by software (or DMA) writing to the [VTNF_CTRL\[0\] EN](#) bitfield, or by SIMCOP HW sequencer sending a pulse on VTNF_start signal. [VTNF_CTRL\[9\] TRIG_SRC](#) must be set to be consistent with the starting mechanism.

Once VTNF starts execution, before it's idle, any further signaling on the start signal or writing to [VTNF_CTRL\[0\] EN](#) bitfield is ignored.

Access to other register fields are optional:

- Revision [VTNF_REVISION](#) (read-only)
- Busy/idle status [VTNF_CTRL\[16\] BUSY](#) (read-only)
- Interrupt enable [VTNF_CTRL\[8\] INTEN](#)
- Autogating [VTNF_CTRL\[10\] AUTOGATING](#)

The VTNF module signals task completion by interrupt and VTNF_done signal. The interrupt is sent only when it's enabled, via [VTNF_CTRL\[8\] INTEN](#). The VTNF_done signal is always sent.

The VTNF provides a busy bit ([VTNF_CTRL\[16\] BUSY](#)) for software to poll the busy/idle status, for debug or for initial software development that bypasses interrupts and hardware sequencer. Relative latency of done, interrupt, and [VTNF_CTRL\[16\] BUSY](#) is within 2 VTNF_CFG_CLK (configuration clock) cycles or 1 VTNF_FCLK cycle (twice the speed of cfg clock).

NOTE: VTNF does not have any shadow registers; as this is a block-based coprocessor, parameters apply to the whole frame and only one set of config registers is constructed. Parameter change should happen in between active frame processing.

9.4.4.4.2 ISS SIMCOP VTNF Programming Ranges and Restrictions

Individual register field restrictions are stated in the VTNF Initialization section. Besides those, SIMCOP programming must provide sufficient image buffer(s) with correct address offset to cover the C, P, and O arrays for VTNF input and output.

The line offset `VTNF_LOFST` should be programmed to be equal to or greater than `BLKW[15:0] VTNF_SZ`

Assuming size = `VTNF_LOFST[15:4] LOFST * VTNF_SZ[31:16] BLKH * 1.5` block size in bytes.

- `C_range = [VTNF_CADR[15:4] ADDR + size - 1]`
- `P_range = [VTNF_PADR[15:4] ADDR + size - 1]`
- `O_range = [VTNF_OADR[15:4] OADR + size - 1]`

`C_range`, `P_range`, `O_range` must map to valid memory.

C and P must not overlap. O can overlap C or P, however, it must be a complete overlap, `O = C` or `O = P`.

Figure 9-199. ISS SIMCOP VTNF C, P, O array memory allocation constraints

vtnf-006

In [Figure 9-199](#), cases (a), (b), and (c) are valid use cases. (a) has no overlap. (b) has complete overlap between O and C. (c) has complete overlap between O and P.

Cases (d) and (e) are invalid use cases. Case (d) has C and P overlap, so VTNF cannot read `C[i]` for certain range of `i`. Case (e) has O and P overlap.

In case overlapping conditions are present to render the use case invalid, outcome is indeterminate.

NOTE: As each block is aligned to 128-bit, over-writing `O[i]` upon `C[i]` or `P[i]` would maximize memory utilization and block size flexibility.

Implementation must take care in luma/chroma read/write accesses so that overlapping cases do work.

9.4.4.4.3 ISS SIMCOP VTNF Resets

There is no software reset. Hardware reset at SIMCOP level resets all configuration registers to default values, and turns VTNF internal state (whatever it is) to idle.

VTNF does not retain any state information from one block to the next block. Therefore if a frame of VTNF is to be terminated, allowing a block to complete processing, then reprogram VTNF with processing parameters for a new frame is sufficient. No reset is needed at all.

9.4.4.4.4 ISS SIMCOP VTNF Programming Parameters Tuning

NOTE: Parameter register fields can be programmed in any order, as long as before the computation is initiated, desired parameter values are in place.

Tuning video quality is mainly in the color weights (VTNF_WEIGHTS[5:0] W1 and W2), rounding bit count (VTNF_CFG[7:4] T), and the two lookup tables VTNF_LUT1_0 to VTNF_LUT2_28 (LUT1[0..31] and LUT2[0..31] bitfields) .

The weights are used to adjust the contribution of luma and chroma differences to the combined start address value, and the combined SAD value is rounded down by T bits for the lookup table index.

The lookup table contents are the alpha blending values to blend the previous frame output and current frame input. Lower value means lower contribution from the previous frame output, 0 means no contribution.

Roughly, low SAD value means the current input pixel does not differ much from previous output pixel of the same location, so the difference is due to noise, and user should blend harder, so the lower index lookup tables should contain larger alpha blending value.

Conversely, high SAD value means the current input pixel differs from previous output pixel of the same location, and this is an indication of moving video contents, so user should not blend at all, and alpha should be 0.

A typical table represents the curve in the Figure 9-200. max_alpha should be between 50% and 75%, to achieve effective noise reduction. index1 should reflect noise threshold, as absolute difference between current input frame pixel and previous output frame pixel beyond this is attributed to moving contents, as opposed to noise. The weights and number of bits to round down are tuned so that max_index falls within the lookup table index.

Between the (0, max_alpha) and (index1, 0) points, how alpha should transition is really up to experimentation and optimization. There should be a gradual down slope, as user want noise spikes with values close the noise threshold to be somewhat reduced, not totally eliminated or totally retained based on boolean decision.

Figure 9-200. ISS SIMCOP VTNF Typical lookup table contents

The two lookup tables are used to blend luma and chroma respectively. Normally user want to blend chroma stronger than luma. Moderate level of luma noise makes the image appears sharper and more pleasing, where as chroma noise appears as color patches, so image would look better if user suppress chroma noise.

9.4.5 ISS SIMCOP LDC Module

This chapter describes the lens distortion correction (LDC) module in the still image coprocessor (SIMCOP) subsystem.

9.4.5.1 ISS SIMCOP LDC Overview

The lens distortion correction (LDC) module deals with lens geometric distortion issues, chromatic aberration, and affine transformation for camera images. [Figure 9-201](#) is an overview of the LDC in the SIMCOP subsystem.

Figure 9-201. ISS SIMCOP LDC Subsystem

For still image or video applications the LDC supports:

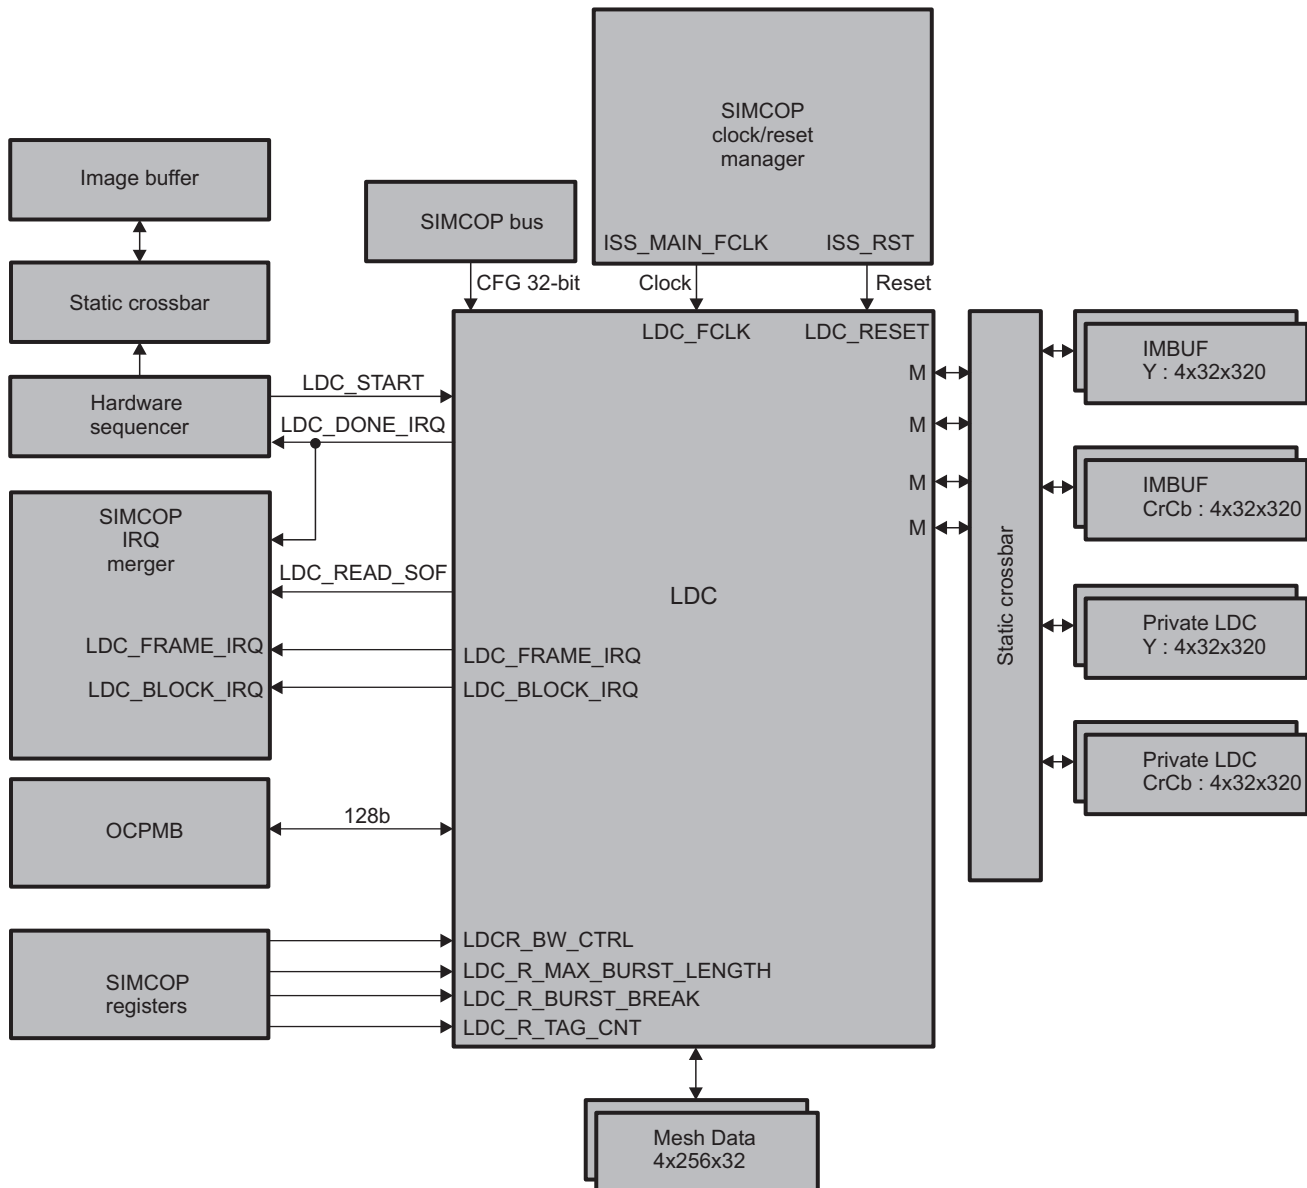

- Lens distortion correction:
 - YCbCr4:2:2/YCbCr4:2:0 data format input/output for post-image-pipe correction
 - Uses a generic distortion model to correct multiple distortion types.
 - 8 bits for YCbCr
 - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
 - Bilinear interpolation mode for Y to offer faster processing
 - Up to 8192 x 8192 image dimension

- Format restriction:
 - YCbCr4:2:2 format: Tile width must be a multiple of 16.
 - YCbCr4:2:0 format: Tile width must be a multiple of 32.
- Image warping, scaling, and rotation:
 - Affine transformation for image warping, scaling, and rotation
 - 8 bits for YCbCr
 - Supports Bayer data in unpacked 12-bit per pixel, 8-bit per pixel A-law, 8-bit per pixel unpacked, and 12-bit per pixel packed formats
 - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
 - Bilinear interpolation mode for Y, Bayer
 - Format restriction:
 - YCbCr4:2:2 format: Tile width must be a multiple of 16.
 - YCbCr4:2:0 format: Tile width must be a multiple of 32.
- Chromatic aberration correction:
 - Supports Bayer data in unpacked 12-bit per pixel, 8-bit per pixel A-Law, 8-bit per pixel unpacked, and 12-bit per pixel packed formats
 - Generic distortion
 - Model is used to describe corrections on red and blue image planes in Bayer image
 - Red and blue distortion only. Green pixels are copied to output.
 - Red and blue distortions are described independently
 - Bilinear interpolation
 - Up to 8192 x 8192 image dimension
 - Format restriction:
 - Unpacked 12-bit format: Tile width must be a multiple of 16.
 - A-Law 8-bit format: Tile width must be a multiple of 32.
 - Unpacked 8-bit format: Tile width must be a multiple of 32.
 - Packed 12-bit format: Tile width must be a multiple of 64.

9.4.5.2 ISS SIMCOP LDC Integration

The LDC module is part of the SIMCOP subsystem in the ISS. [Figure 9-202](#) shows the integration of the LDC in the SIMCOP subsystem.

For more information about interrupt requests, see [Section 9.4.1.2.3](#), *Interrupt Merger*.

9.4.5.3 ISS SIMCOP LDC Functional Description

9.4.5.3.1 ISS SIMCOP LDC Block Diagram

Most digital cameras suffer from some degree of nonlinear geometric distortion. A spatial transformation is required to correct the distortion. In automotive applications, cameras use wide angle lenses, including fisheye lenses to provide 180+° field of view. To visually present the scene to the user in an easy-to-consume representation, these distortions need to be corrected.

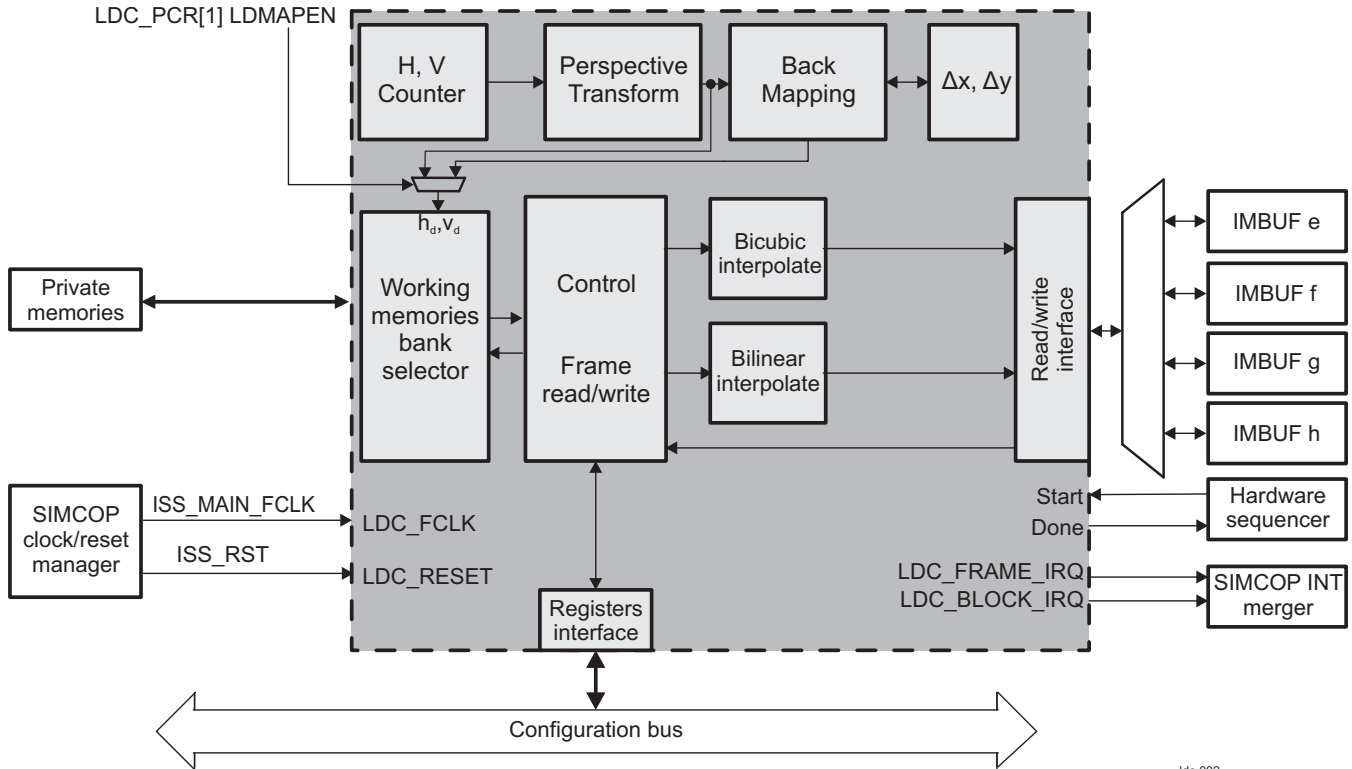

Back mapping gives coordinates of the distorted image as a function of coordinates of the undistorted output image. Correction involves back-mapping each output pixel to a location in the source distorted image, and thus the corrected image is fully populated. As the distorted pixel locations mostly fall onto fractional coordinates, correction involves interpolation among the nearest available pixels.

For any distortion, the user must determine the overlap between the distorted space and the input image coordinates. Valid image data is produced only for those points where the distorted space lies completely within the valid input image.

As shown in [Figure 9-203](#), the LDC consists of a back mapping block, a x/y offset table, image buffer interface, buffer, and an interpolation block.

[Figure 9-203](#) is a block diagram of the LDC.

Figure 9-203. ISS SIMCOP LDC Block Diagram

ldc-002

Given the coordinates of the undistorted image, the corresponding coordinates of the distorted image are calculated by combining the output coordinates and the offsets from the offset table. Distorted pixels are read from the image buffer, and buffered for the bilinear interpolation. After the interpolation, corrected image is written back to the image buffer.

The LDC processes the image in small two-dimensional (2D) blocks. The software configures appropriate parameters, then initiates the LDC function by writing to an LDC register. The LDC controls the sequencing through 2D blocks, DMA transfers, and computation to process an entire image autonomously. Interrupt, if enabled, is asserted at the completion of the image.

The LDC can also be stalled and controlled on a macroblock basis by an external controller. The LDC provides an intermediate interrupt to facilitate this. The LDC can be stalled by deasserting the write request enable on the output write port.

To start the LDC, software must set the [LDC_PCR\[0\] EN](#) bit to 1. The [LDC_PCR\[2\] BUSY](#) bit is a status that reflects LDC activity.

9.4.5.3.2 ISS SIMCOP LDC Interrupt Requests

[Table 9-2769](#) lists the event flags, and their mask, that can cause module interrupts.

Table 9-2769. ISS SIMCOP LDC Events

Event Flag	Event Mask	Map to	Description
n/a	N/A	LDC_FRAME_IRQ	End of frame processing
n/a	N/A	LDC_BLOCK_IRQ	End of macroblock processing

9.4.5.3.3 ISS SIMCOP LDC Input/Output Format Data

9.4.5.3.3.1 ISS SIMCOP LDC YCbCr Format

The LDC supports YCbCr4:2:2 in the UYVY format. Figure 9-204 shows the UYUV format in memory.

Figure 9-204. YCbCr4:2:2 (UYVY) Format

		Byte offset						
		0	1	2	3	4	5	6
Row 0		Cb(0,0)	Y(0,0)	Cr(0,0)	Y(1,0)	Cb(2,0)	Y(2,0)	Cr(2,0)
Row 1		Cb(0,1)	Y(0,1)	Cr(0,1)	Y(1,1)	Cb(2,1)	Y(2,1)	Cr(2,1)

ldc-003

The LDC supports YCbCr4:2:0 data stored in 8-bit per color components and in two planes, Y by itself and Cb/Cr interleaved. Figure 9-205 shows the NV12 format in memory.

Figure 9-205. ISS SIMCOP LDC YCbCr4:2:0 (NV12) Format

		Byte offset			
Y plane		0	1	2	3
Row 0		Y(0,0)	Y(1,0)	Y(2,0)	Y(3,0)
Row 1		Y(0,1)	Y(1,1)	Y(2,1)	Y(3,1)
Cb/Cr plane		⋮			
Row 0		U(0,0)	V(0,0)	U(2,0)	V(2,0)
Row 1		U(0,2)	V(0,2)	U(2,2)	V(2,2)

ldc-004

9.4.5.3.3.2 ISS SIMCOP LDC Bayer Format

The LDC supports Bayer data processing. In this mode, only the red and blue channels can be distorted. The LDC copies the original green pixels to the output image without modification. The mesh table provides pixel shift information for both the red and the blue channels. The starting pixel color is configurable (see Figure 9-206). This mode supports chromatic aberration correction by aligning the red and blue channels with the green channel.

Figure 9-206. ISS SIMCOP LDC Supported Bayer Data Format (Starting Color)

R	Gr	R	Gr	Gr	R	Gr	R
Gb	B	Gb	B	B	Gb	B	Gb
R	Gr	R	Gr	Gr	R	Gr	R
Gb	B	Gb	B	B	Gb	B	Gb
Gb	B	Gb	B	B	Gb	B	Gb
R	Gr	R	Gr	Gr	R	Gr	R
Gb	B	Gb	B	B	Gb	B	Gb
R	Gr	R	Gr	Gr	R	Gr	R

ldc-006

Bayer mode can support Bayer data in several formats. For supported data format in memory, see Figure 9-207.

Figure 9-209. ISS SIMCOP LDC Forward A-Law (10-Bit to 8-Bit)

9.4.5.3.4 ISS SIMCOP Lens Distortion Back-Mapping

Both modes of LDC, YCbCr mode and Bayer mode use offset tables to define the back mapping between output pixel locations and input pixel locations. The contents of the tables differ between the two modes. These modes are described in the next sections.

9.4.5.3.5 ISS SIMCOP LCD Bayer Chromatic Aberration Correction Implementation

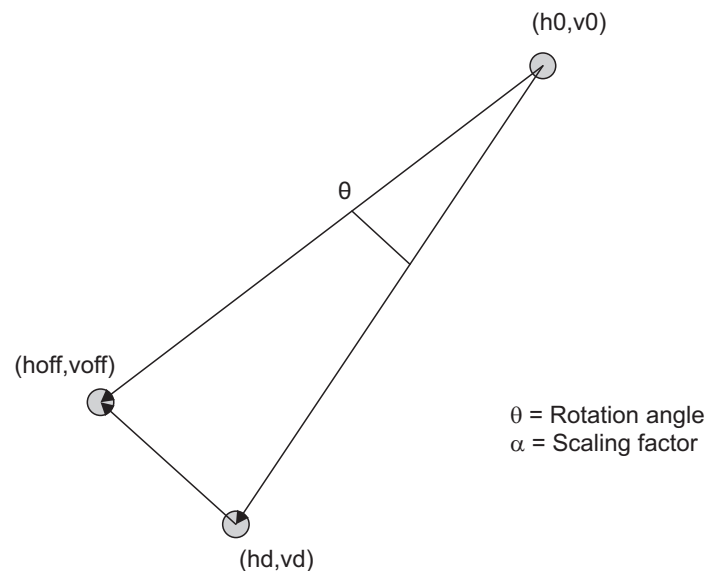

The implementation of Bayer mode CAC differs slightly from the YCbCr mode used for distortion correction. Because there are three colors in the image and only two are being modified, the details for calculating the input bounding box must be specified separately. The affine transform is disabled internally, so the mesh interpolation is the only transformation on the coordinates. For each output tile, the four corners are analyzed to determine the input bounding box. In Bayer mode, the corner is defined by a 2x2 Bayer block. The red and blue coordinates are transformed using the mesh table calculation. A third coordinate is the original location of the corner, defined as the location of the actual corner pixel with no transform applied. FIGURE shows this, with the corner pixels marked with a dot. This gives 12 coordinates for each output tile. The bounding box is determined by finding the minimum and maximum for both x and y. These four numbers then determine the range of the input bounding box. To this bounding box, the PIXPAD parameter adds additional pixels.

Figure 9-210 (a) Example output tile of Bayer data. Each corner is a 2x2 Bayer block. The four corner pixels used in the calculation are marked with a dot. (b) In each corner, red and blue pixels within the Bayer block are transformed using the mesh calculation. After transformation, the minimum and maximum of all of the final 12 x locations is used as the horizontal range of the bounding box. The minimum and maximum of all of the final 12 y locations is used as the vertical range of the bounding box. The dotted line shows the computed input bounding box. PIXPAD adds pixels around this prior to fetching input data.

Figure 9-210. Example output tile of Bayer data

9.4.5.3.6 ISS SIMCOP LDC Affine Transform

The LDC first performs an affine transform, which can be used for rotations and scaling, as shown in Figure 9-211. The output of the pixel coordinate is used as the input address to the affine transform.

Figure 9-211. Affine Transformation

$$\begin{bmatrix} h_{off} \\ v_{off} \end{bmatrix} = \begin{bmatrix} a \times \cos(\theta) & a \times \sin(\theta) \\ -a \times \sin(\theta) & a \times \cos(\theta) \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_0 - h_0 \times a \times \cos(\theta) - v_0 \times a \times \sin(\theta) \\ v_0 + h_0 \times a \times \cos(\theta) - v_0 \times a \times \sin(\theta) \end{bmatrix}$$

ldc-010

The mapping from destination coordinate to the source coordinate is expressed as:

$$h_{aff} = a \times h_d + b \times v_d + c$$

$$v_{\text{aff}} = d \times h_d + e \times v_d + f$$

This transform allows full rotation, expansion, contraction, and translation. The parameters {a, b, d, e} are in S16Q12 (signed number on 14 bits with 2 bits for integer and 12 bits of fraction) format, and parameters {c, f} are in S16Q3 format (signed number on 16 bits with 13 bits for integer and 3 bits of fraction). These parameters must be set in following bit fields:

- a = LDC_AB[13:0] A
- b = LDC_AB[29:16] B
- c = LDC_CD[15:0] C
- d = LDC_CD[29:16] D
- e = LDC_EF[13:0] E
- f = LDC_EF[31:16] F

NOTE: The affine transform is not supported in Bayer mode.

9.4.5.3.7 ISS SIMCOP LDC Perspective Transformation

When a camera is viewing a scene from two different positions or when multiple cameras are viewing the scene from different positions, a transformation between the two viewing angles is needed to align the images. Under specific conditions, the class of geometric transformations known as homography, or planar-perspective transformation, will capture the geometric relationship between the images accurately. Common applications of homography transforms are to align (or stitch) multiple frames of the same scene to compute a panoramic output image. A second application is the alignment of planar surfaces in the world. Finally, perspective transforms are also useful in computing depth maps from a stereo image pair. By rectifying the two views, the search to compute disparity between the two views is simplified to a 1-D search problem. The homography is defined by a 3x3 transformation matrix, as in

$$h_{\text{aff}} = a * h_d + b * v_d + c \tag{4}$$

$$v_{\text{aff}} = d * h_d + e * v_d + f \tag{5}$$

$$z = g * h_d + h * v_d + 1 \tag{6}$$

-

$$h_p = h_{\text{aff}} / z \tag{7}$$

$$v_p = v_{\text{aff}} / z. \tag{8}$$

The affine transform is a subset of the perspective transformation. By setting $g = h = 0$, $h_p = h_{\text{aff}}$ and $v_p = v_{\text{aff}}$.

In image alignment applications, the homography matrices are computed by locating corresponding points in the two frames and estimating the matrix parameters to transform the set of points in one frame onto the corresponding points in the second frame. In the stereo rectification application, the matrix is determined (pre-computed) at the calibration step and remains fixed.

When LDC is requested to provide a change in the frame size between the input and output, the affine/perspective parameters must be programmed to implement the coordinate scaling (see [Section 9.4.5.4.5](#) for programming details) . The perspective transform is not supported in Bayer mode. This function is disabled inside the HW design.

9.4.5.3.8 ISS SIMCOP LDC Pixel Interpolation

In UYVY and NV12 mode, the pixel interpolation type can be set to bicubic interpolation for best quality or bilinear interpolation for faster performance. In Bayer mode, bilinear interpolation is always used.

As the coordinates (h_{aff} , v_{aff}) calculated by the back-mapping function are not generally integer values, bicubic or bilinear interpolation is applied to the distorted pixels.

Depending on register configuration, bicubic or bilinear interpolation is used to interpolate the output Y pixels:

- LDC_CONFIG[6] YINT_TYP = 0, bicubic interpolation for Y, bilinear for other components
- LDC_CONFIG[6] YINT_TYP = 1, bilinear interpolation for all components

In the case of bicubic interpolation, the distorted pixel is interpolated from the 16 Y pixels in the 4 x 4 grid around the distorted location, as shown in [Figure 9-212](#). Bicubic interpolation is used first along the horizontal direction, then the vertical direction.

Figure 9-212. ISS SIMCOP LDC Bicubic Interpolation for Y

If bilinear interpolation is selected, the distorted pixel is interpolated from the four Y pixels in the 2 x 2 grid around the distorted location, as shown in [Figure 9-213](#).

Figure 9-213. ISS SIMCOP LDC Bilinear Interpolation for Y

For Cb and Cr components, simple bilinear interpolation is used. Each distorted pixel is interpolated from the four same-color pixels on the 2 x 2 grid around the distorted location. For UYVY data, the Cb/Cr grid is not square, but is 2x wider compared to the height. This is shown in [Figure 9-214](#).

Figure 9-214. ISS SIMCOP LDC Bilinear Interpolation for CB/Cr in UYVY and NV12 Format

ldc-013

In Bayer mode processing, bilinear interpolation is used. The red and blue distorted pixels are interpolated from the four same-color pixels on the 2 x 2 grid around the distorted location.

9.4.5.3.9 ISS SIMCOP LDC Buffer Management

The LDC processes a block of $LDC_BLOCK[7:0]$ OBW x $LDC_BLOCK[15:8]$ OBH (output block width by output block height) pixels at a time in a raster-scan order throughout the image. OBW is constrained to be a multiple of a base width, depending on the operating mode. This is described in [Table 9-2770](#). OBH should be even. The LDC uses four corners of the output block plus some padding to fetch the input block. Software must supply OBW, OBH, and $LDC_BLOCK[19:16]$ PIXPAD, the amount of padding in input pixels. Software must guarantee that, for EVERY output pixel in the OBW x OBH output block, the input pixels required are bounded by back mapping of the four corners plus/minus the padding. More precisely, the input block is determined by:

- $IBX_start = \min(\text{truncate}(\text{distortx}(\text{corner1})), \text{truncate}(\text{distortx}(\text{corner3}))) - \text{PixelPad}$
- $IBX_end = \max(\text{truncate}(\text{distortx}(\text{corner2})), \text{truncate}(\text{distortx}(\text{corner4}))) + \text{PixelPad}$
- $IBY_start = \min(\text{distorty}(\text{corner1}), \text{truncate}(\text{distorty}(\text{corner2}))) - \text{PixelPad}$
- $IBY_end = \max(\text{truncate}(\text{distorty}(\text{corner3})), \text{truncate}(\text{distorty}(\text{corner4}))) + \text{PixelPad}$

where corner1, corner2, corner3, and corner4 are upper-left, upper-right, lower-left, and lower-right corners of the OBW x OBH output block, and $\text{distortx}(\cdot)$, $\text{distorty}(\cdot)$ are X and Y distorted coordinates of the corners. Distorted coordinates computed by the back-mapping process described in [Section 9.4.5.3.4, ISS SIMCOP Lens Distortion Back-Mapping](#). [Figure 9-215](#) shows the input block bound calculation. [Table 9-2770](#) lists the OBW requirements.

Figure 9-215. ISS SIMCOP LDC Input Block Bound

Table 9-2770. ISS SIMCOP LDC OBW Requirements

Data Format	OBW must be a multiple of
YCbCr4:2:2	8
YCbCr4:2:0	16
Bayer unpack	8
Bayer 8-bit	16
Bayer A-Law	16
Bayer 12-bit	32

Typically for geometric distortion, the `LDC_BLOCK[19:16]` PIXPAD bit field must be 4 to accommodate neighbor sets for all colors. Chromatic aberration, where the back-mapping depends on the color of output pixel, incurs additional levels in PIXPAD. For example, to correct 3 pixels of chromatic aberration, specify `PIXPAD = 4 + 3 = 7`. Software must set the PIXPAD bit field correctly.

NOTE: A tool is available to calculate PIXPAD for a given frame size and distortion mapping. Another utility is provided with the functional C model that computes the minimum PixelPad given a configuration and the processing block size: OBW, OBHT. To obtain these tools, contact your TI representative.

OBH and OBW must be large enough for efficient operation of the lens distortion operation. As shown in [Table 9-2770](#), OBW is constrained to ensure efficient external memory write. Another constraint is that input block size, $(IBX_end - IBX_start + 1) \times (IBY_end - IBY_start + 1)$, for EVERY input block of the image, must fit the allocated input buffer. These parameters must not be specified pessimistically (OBH, OBW too small, or PixelPad too large). Pessimistic parameter setting degrades performance and incurs unnecessary external memory transfer.

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image.

An intermediate interrupt can occur after processing each macroblock. This lets the LDC operation be pipelined with other tasks.

To process only a portion of the image, the following parameters are required:

- `LDC_INITXY[13:0]` INITX: X coordinate of upper-left corner of output frame
- `LDC_INITXY[29:16]` INITY: Y coordinate of upper-left corner of output frame
- `LDC_FRAME_SIZE[13:0]` W: Width of output frame
- `LDC_FRAME_SIZE[29:16]` H: Height of output frame
- `LDC_WR_BASE[31:0]` WBASE: SDRAM address of upper-left corner of output frame (Y and Cb/Cr base required for YCbCr4:2:0: `LDC_420C_WR_BASE[31:0]` WBASE)
- `LDC_WR_OFST[15:0]` WOFST: SDRAM frame width (in bytes)

[LDC_FRAME_SIZE\[13:0\]](#) W must be a multiple of [LDC_BLOCK\[7:0\]](#) OBW, [LDC_FRAME_SIZE\[29:16\]](#) H a multiple of [LDC_BLOCK\[15:8\]](#) OBH, and [LDC_WR_BASE\[31:0\]](#) WBASE a multiple of 32 (byte address)

Figure 9-216 is an example of multiple-pass processing with middle-of-the-image skipped.

Figure 9-216. ISS SIMCOP LDC Multiple-Pass Correction Example

INITX	INITY	W	H	WBASE
0	0	32	72	0x10000
32	0	48	12	0x10040
80	0	32	72	0x100A0
32	60	48	12	0x134C0

ldc-015

The LDC does not copy skipped blocks from the input frame to the output frame (necessary task unless output frame = input frame); software must set up and initiate this memory copy.

A note on in-place operation to conserve external memory: Depending on the offset table and configuration parameters, it may not be feasible to point the output image at the input image and have corrected pixels overwriting the source image. Software must determine whether it is feasible to overwrite, and allocate a separate frame buffer when it is not feasible. The LDC does not care if the input and output image pointers coincide, nor does it check any dependency violations.

The starting address of the input frame, corresponding to input coordinate (0, 0), is specified in the [LDC_RD_BASE\[31:0\]](#) RBASE bit field and offset in the [LDC_RD_OFST\[15:0\]](#) ROFST bit field ((Y and Cb/Cr base required for YCbCr4:2:0: [LDC_420C_RD_BASE\[31:0\]](#) RBASE)). The LDC does not check whether any of the input block falls outside the input frame. Software must pad the input frame with zeros or borders, if an input block falls outside the input frame, so that there is no adverse effect in the corrected image.

NOTE:

- Each input block bounding box, as defined by distorted coordinate of output corners plus the pixel pad, is NEVER to be violated in the sense that any output pixel in the block must have interpolation source pixels from the input block.
- Any number of input blocks CAN fall partially or totally outside the input frame by assuming coordinates that are outside valid range (negative or exceeding maximum image width defined by the line offset).
- If any output pixel refers to any input pixel outside the input frame, the computed value for that output pixel is not guaranteed. The other output pixels can still have correct outcomes.

9.4.5.3.10 ISS SIMCOP LDC Input Circular Buffer

To better enable slice-based processing with a random access algorithm such as LDC/perspective warp, LDC module must be able to read its input image data from a circular buffer. The amount of data needed by LDC module depends on the configuration and the warp factors, so there is a variable rate of input data consumed by LDC during processing of an entire frame.

The [LDC_RD_OFST\[29:16\] MOD](#) parameter controls the size of the circular buffer (in number of rows, must be even). The user sets the size of the circular buffer and the absolute address for the input data is then computed by:

$$\text{Address} = \text{base} + (\text{row} \% \text{LDC_RD_OFST}[29:16] \text{ MOD}) * \text{line_offset} + \text{column}$$

NV12 or NV21 Modes In NV12 or NV21, the image data is split between two buffers, the luma plane and the interleaved chroma plane. The [LDC_RD_OFST\[29:16\] MOD](#) register computes the size of the luma plane. By definition, the chroma plane is half the height of the luma plane. The modulo operation for the chroma plane uses [LDC_RD_OFST\[29:16\] MOD/2](#) as the divisor.

UYVY and Bayer Modes In UYVY mode, the image data is in a single buffer. Therefore, the [LDC_RD_OFST\[29:16\] MOD](#) register directly gives the height (in rows) of the buffer.

In Bayer mode, the image data is also in a single buffer, so the circular buffer height can be directly set by [LDC_RD_OFST\[29:16\] MOD](#) register.

To enable circular addressing mode, the firmware must configure [LDC_PCR\[9\] CIRCEN = 1](#). It is the responsibility of the firmware to ensure that the circular buffer size is sized appropriately for the given LDC configuration. If the buffer size is set too small, incorrect data output is expected.

Circular buffering is only supported for the input image data. Mesh table data is not read through a circular buffer.

9.4.5.3.11 ISS SIMCOP LDC and Hardware Sequencer

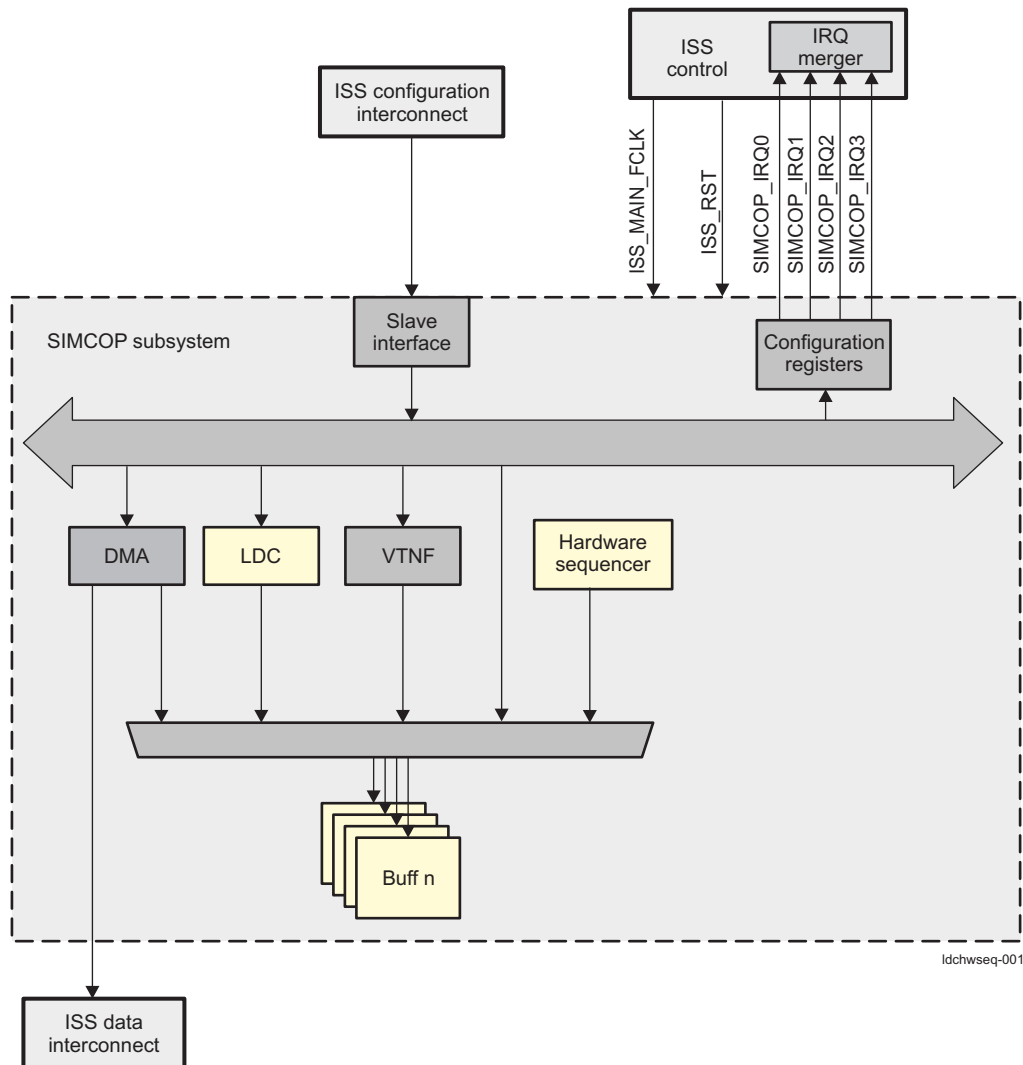

NOTE: This section provides only LDC associated functionality, for details of Hardware Sequencer and its configuration refer to *ISS SIMCOP Hardware Sequencer and Buffers Module* in the device TRM.

9.4.5.3.11.1 ISS SIMCOP LDC and Hardware Sequencer and Buffers Overview

The SIMCOP hardware sequencer control all the modules included in the SIMCOP subsystem with their memories.

[Figure 9-217](#) shows an overview of the hardware sequencer and buffers along the LDC in the SIMCOP subsystem.

Figure 9-217. LDC and Hardware Sequencer and Buffers in the SIMCOP Subsystem

- Hardware acceleration for low-level sequencing tasks:
 - Synchronizes with LDC, DMA, and VTNF
 - Supports 4 memory crossbar contexts
- Power management support
- On chip memories (RAM):
 - LDC look-up table storage: 256 entries

9.4.5.3.11.2 ISS SIMCOP LDC and Hardware Sequencer and Buffer Integration

The hardware sequencer and buffers module is part of the SIMCOP subsystem in the ISS.

Figure 9-218 shows the integration of the hardware sequencer and buffers in the SIMCOP subsystem.

Figure 9-218. ISS SIMCOP LDC and Hardware Sequencer and Buffer Integration

9.4.5.3.11.3 ISS SIMCOP LDC and Hardware Sequencer and Buffers Functional Description

9.4.5.3.11.3.1 ISS SIMCOP Hardware Sequencer Buffer Description

The SIMCOP subsystem includes the LDC private working memory

9.4.5.3.11.3.1.1 ISS SIMCOP LDC Static Crossbar

The static crossbar connect SIMCOP modules to the SIMCOP memories as shown in [Figure 9-219](#).

Figure 9-219. SIMCOP Static Crossbar Overview

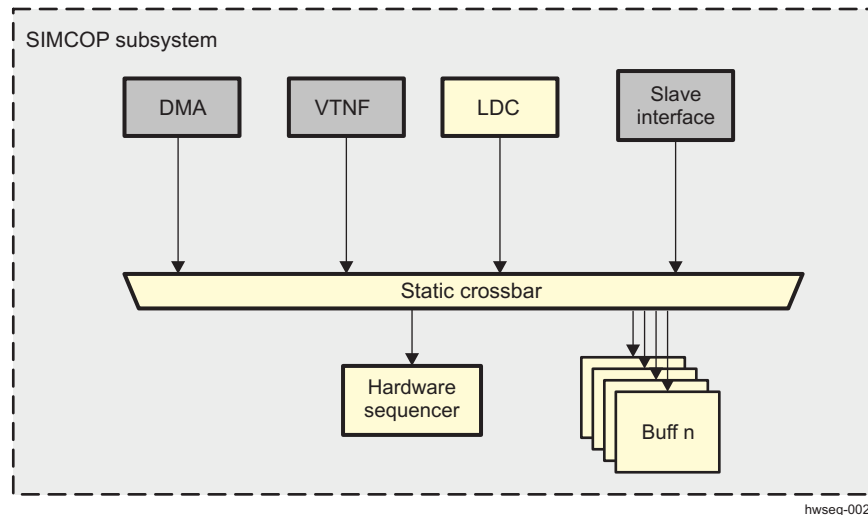

Image buffers and coefficient memories are used to store the data to be processed and processing results. Those memories can be accessed by the SIMCOP DMA, SIMCOP bus, and SIMCOP modules. [Table 9-2771](#) shows possible connections in the SIMCOP static crossbar. For example, the LDC Freq port could access image buffer a when $\text{SIMCOP_HWSEQ_SWITCH_i}[2:0] \text{IMBUFF_E} = 0x6$ ($i = 0, 1, 2, \text{ or } 3$ corresponds to the active context).

The SIMCOP supports multiple contexts for the configuration of those memories. Software or the hardware sequencer can activate different contexts.

Table 9-2771. Static Crossbar Control Summary (2/2)

Memory	Register (SIMCOP_HWSEQ_STEP_SWITCH_i and SIMCOP_HWSEQ_STEP_CTRL2_i)	Value				
		Bus	DMA	LDC 0	LDC WMEM	VTNF
IMBUFF e	[18:16] IMBUFF_E	0	1	6	-	8
IMBUFF f	[22:20] IMBUFF_F	0	1	6	-	8
IMBUFF g	[27:24] IMBUFF_G	0	1	9	-	8
IMBUFF h	[31:28] IMBUFF_H	0	1	9	-	8

9.4.5.3.11.3.1.2 ISS SIMCOP LDC Private Input Memory

The LDC has a private input memory that can be used when the LDC operates in YUV4:2:0 mode. For YUV4:2:2 and RAW operation, the LDC must use image buffers as input memories.

The LDC input memory is dedicated for LDC operation. It cannot be accessed from the SIMCOP bus or by any other SIMCOP module.

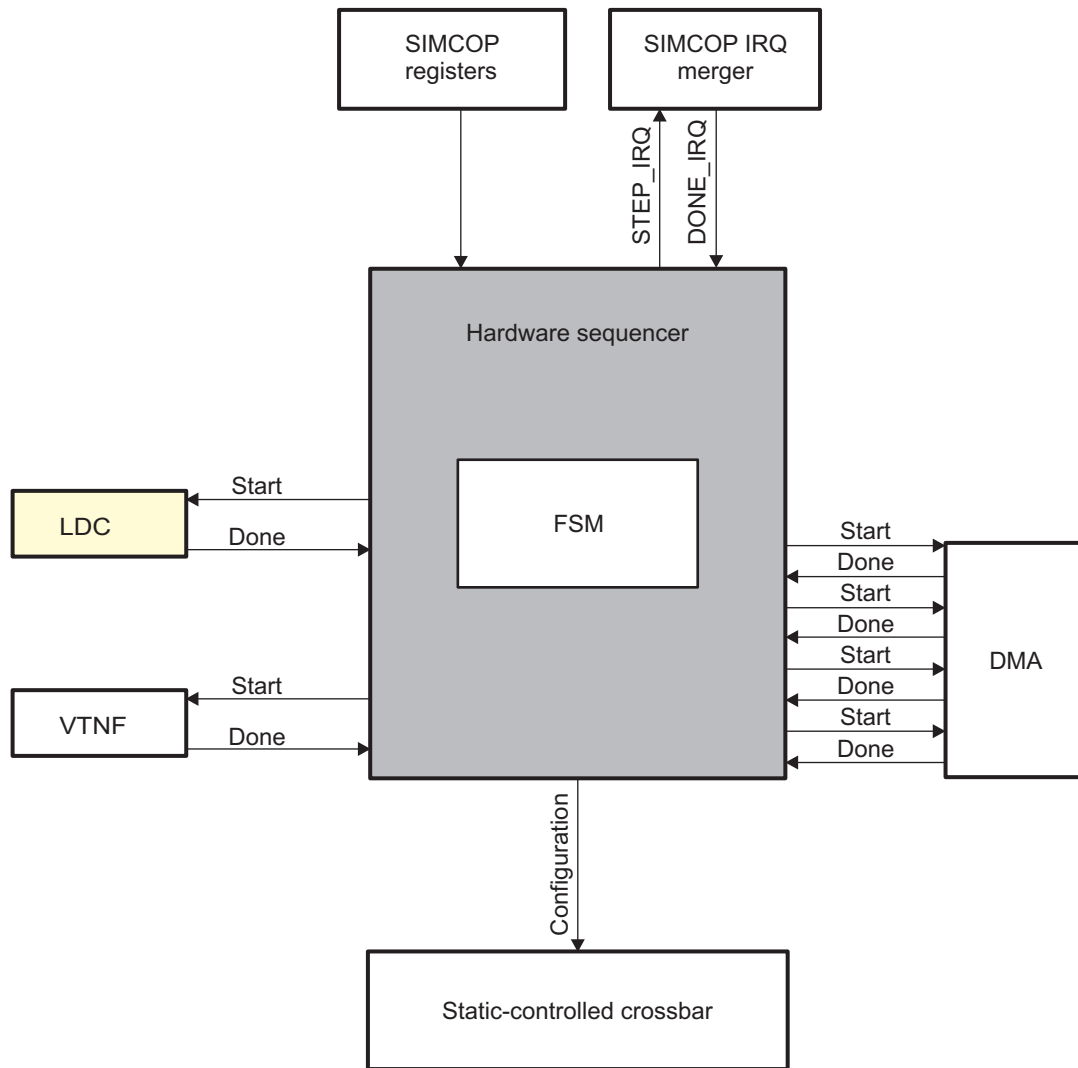

9.4.5.3.11.3.2 ISS SIMCOP Hardware Sequencer

The SIMCOP typically processes a full frame on a macroblock-by-macroblock basis. The SIMCOP modules and the DMA controller trigger an interrupt when they have completed a macroblock. This event can either trigger an interrupt to an external initiator (CPU) (manual mode) or trigger a context switch and resume DMA/SIMCOP module processing. Typically, initiator intervention is needed to fill the macroblock pipeline (called pipe-up, that is, the first n macroblocks of an image) and to flush the macroblock pipeline (called pipe-down, that is, the last n macro-blocks of an image). Automatic sequencing mode is typically used for the rest of the image.

The hardware sequencer is particularly useful to offload the initiator during LDC processing.

Figure 9-220 depicts the SIMCOP hardware sequencer overview.

Figure 9-220. SIMCOP Hardware Sequencer Overview

The hardware sequencer can automatically execute a predefined number of sequencing steps without software intervention. This is called automatic operation. Automatic operation can also be used for pipeline filling and flushing with some limited software intervention. During automatic operation, the hardware sequencer controls the generation of START/DONE pulses and the connections in the static controlled crossbar. Software can take control over some resources while the hardware sequencer is running. This is called hardware sequencer override.

9.4.5.3.11.3.2.1 Hardware Sequencer Override

By default, the hardware sequencer controls START/DONE pulses of all SIMCOP modules as well as the static controlled crossbar. Software can take the control over some resources by setting the appropriate bits in the SIMCOP_HWSEQ_OVERRIDE register. Sequencing resources under software control are managed using the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers.

Changes done to the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[27:11] *_OFST and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers have immediate effect. It is the responsibility of software to ensure there is no active traffic on the impacted connection in the static controlled crossbar.

The settings in the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers for resources controlled by the hardware sequencer have no effect.

Synchronization with SIMCOP submodules is controlled using the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[7:0] *_TRIGGER bit fields. For LDC a START pulse is sent to the module when a 1 is written into the appropriate bit field. Software can trigger one or multiple start pulses at the time. The *_TRIGGER bit field is cleared by writing 1. It is automatically set by hardware when a DONE pulse is received from the relevant SIMCOP submodule.

9.4.5.4 ISS SIMCOP LDC Basic Programming Model

9.4.5.4.1 ISS SIMCOP LDC Initialization of Surrounding Modules

To initialize the LDC, surrounding modules must be initialized. [Table 9-2772](#) lists these modules.

Table 9-2772. ISS SIMCOP LDC Initialization of Surrounding Modules

Module	Minimum Required Setting	Optional Settings
CLKC	Enable the SIMCOP clock.	
Buffers	Configure LDC access to the image buffer.	
SIMCOP CTRL		Configure SIMCOP CTRL to handle LDC interrupts.

9.4.5.4.2 ISS SIMCOP LDC Geometric Distortion Mode

Geometric distortions (barrel and pincushion), can be corrected on UYVY and NV12 data formats. Radial back mapping is used in this mode. An additional affine transform can be configured at the same time.

1. Check and wait for the [LDC_PCR\[2\]](#) BUSY bit to become IDLE (0x0).
2. Set the [LDC_PCR\[4:3\]](#) MODE bit field for UYVY (0x0) or NV12 data (0x2).
3. Set the [LDC_PCR\[1\]](#) LDMAPEN bit to 1 to enable lens distortion back mapping.
4. Set the input frame base address in the [LDC_RD_BASE\[31:0\]](#) RBASE bit field. The frame base address must be aligned on a 32-byte boundary.
5. Set the input frame line offset in the [LDC_RD_OFST\[15:0\]](#) ROFST bit field.
6. If reading the input image from a circular buffer:
 - Set [LDC_PCR\[9\]](#)CIRCEN = 1.
 - LDC computes the row number and applies a modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in [LDC_RD_OFST.MOD](#). In UYVY mode, the number of rows in the buffer is [LDC_RD_OFST.MOD](#). In NV12 and NV21 modes, the number of rows in the Y buffer is [LDC_RD_OFST.MOD](#) and the number of rows in the Cb/Cr buffers is ([LDC_RD_OFST.MOD](#) / 2).
7. Set the tile size in the [LDC_BLOCK\[15:8\]](#) OBH and [LDC_BLOCK\[7:0\]](#) OBW bit fields. See constraints on OBW in [Table 9-2770](#)
8. Set the pixel pad in the [LDC_BLOCK\[19:16\]](#) PIXPAD bit field.
9. Set the input frame size in [LDC_INPUT_FRAME_SIZE\[29:16\]](#) H and [LDC_INPUT_FRAME_SIZE\[13:0\]](#) W.
10. Set the output frame size in the [LDC_FRAME_SIZE\[29:16\]](#) H and [LDC_FRAME_SIZE\[13:0\]](#) W bit fields. H and W values must be multiples of OBH and OBW, respectively.
11. Set the starting output point in the [LDC_INITXY\[13:0\]](#) INITX and [LDC_INITXY\[29:16\]](#) INITY bit fields.
12. Set the output frame starting address in the [LDC_WR_BASE\[31:0\]](#) WBASE bit field. The output frame must be 32-byte aligned.
13. Set the output frame line offset in the [LDC_WR_OFST\[15:0\]](#) WOFST bit field.
14. If the data format is NV12, set the 4:2:0 UV input plane base address in the [LDC_420C_RD_BASE\[31:0\]](#) RBASE bit field. This address must be 16-byte aligned.
15. If the data format is NV12, set the 4:2:0 UV output plane base address in the [LDC_420C_WR_BASE\[31:0\]](#) WBASE bit field. This address must be 16-byte aligned.
16. Set the mesh offset table pointer to the correct address ([LDC_MESHTABLE_BASE\[31:0\]](#) BASE and [LDC_MESHTABLE_OFST\[15:0\]](#) OFST). Set the table downsampling factor for MxM downsampling in [LDC_MESHTABLE_CONFIG\[2:0\]](#) M.
17. If the LDC is connected to image buffers where the output address is not updated for each tile, set the constant mode to 0x1 in the [LDC_CONFIG\[7\]](#) CNST_MD bit field.
18. Set the Y plane interpolation type to bilinear or bicubic in the [LDC_CONFIG\[6\]](#) YINT_TYP bit.

19. If also using affine transform, set the six affine transform parameters in the following bit fields:

- [LDC_AB\[13:0\]](#) A
- [LDC_AB\[31:16\]](#) B
- [LDC_CD\[15:0\]](#) C
- [LDC_CD\[31:16\]](#) D
- [LDC_EF\[13:0\]](#) E
- [LDC_EF\[31:16\]](#) F

If affine transform is not used, these need to be set to the following values:

- [LDC_AB\[15:0\]](#) A = 4096
- [LDC_AB\[31:16\]](#) B = 0
- [LDC_CD\[15:0\]](#) C = 0
- [LDC_CD\[31:16\]](#) D = 0
- [LDC_EF\[15:0\]](#) E = 4096
- [LDC_EF\[31:16\]](#) F = 0

20. Set [LDC_PCR\[0\]](#) EN = 1 to start the LDC operation.

21. Wait for the [LDC_PCR\[2\]](#) BUSY bit to become IDLE (0x0) or wait for the completion interrupt.

9.4.5.4.3 ISS SIMCOP LDC Bayer Chromatic Aberration Mode

In Bayer chromatic aberration mode, the red and blue image planes are warped to align with the green image. The radial back-mapping is the main utility for this, although the affine transform can also be used.

1. Check and wait for the [LDC_PCR\[2\]](#) BUSY bit to become IDLE (0x0).
2. Set the [LDC_PCR\[4:3\]](#) MODE bit field for Bayer (0x1).
3. Set the [LDC_PCR\[6:5\]](#) BMODE bit field according to the Bayer format (3: 8-bit A-Law, 2: Packed 8-bit, 1: Packed 12-bit, or 0: Unpacked 12-bit).
4. Set the [LDC_CONFIG\[5:4\]](#) INITC bit field to the initial Bayer color (3: B, 2: Gb, 1: Gr, or 0: R).
5. If lens distortion correction is performed at the same time as the affine transform, set the [LDC_PCR\[2\]](#) LDMAPEN bit to 1. Otherwise, set the [LDC_PCR\[1\]](#) LDMAPEN bit to 0.
6. Set the input frame base address in the [LDC_RD_BASE\[31:0\]](#) RBASE bit field. The frame base address must be aligned on a 16-byte boundary.
7. Set the input frame line offset in the [LDC_RD_OFST\[15:0\]](#) ROFST bit field.
8. If reading the input image from a circular buffer:
 - [LDC_PCR\[9\]](#) CIRCEN = 1
 - LDC computes the row number and applies a modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in [LDC_RD_OFST.MOD](#). In Bayer mode, the number of rows in the buffer is [LDC_RD_OFST.MOD](#).
9. Set the tile size in the [LDC_BLOCK\[15:8\]](#) OBH and [LDC_BLOCK\[7:0\]](#) OBW bit fields. See constraints on OBW in [Table 9-2770](#).
10. Set the pixel pad in the [LDC_BLOCK\[19:16\]](#) PIXPAD bit field.
11. Set the input frame size in [LDC_INPUT_FRAME_SIZE\[29:16\]](#) H and [LDC_INPUT_FRAME_SIZE\[13:0\]](#) W.
12. Set the output frame size in the [LDC_FRAME_SIZE\[29:16\]](#) H and [LDC_FRAME_SIZE\[13:0\]](#) W bit fields. H and W values must be multiples of OBH and OBW, respectively.
13. Set the starting output point in the [LDC_INITXY\[13:0\]](#) INITX and [LDC_INITXY\[29:16\]](#) INITY bit fields.
14. Set the output frame starting address in the [LDC_WR_BASE\[31:0\]](#) WBASE bit field. The output frame must be 16-byte aligned.
15. Set the output frame line offset in the [LDC_WR_OFST\[15:0\]](#) WOFST bit field.
16. Set the mesh offset table pointer to the correct address ([LDC_MESHTABLE_BASE\[31:0\]](#) BASE and [LDC_MESHTABLE_OFST\[15:0\]](#) OFST). Set the table downsampling factor for MxM downsampling in

LDC_MESHTABLE_CONFIG[2:0] M.

17. If the LDC is connected to image buffers where the output address is not updated for each tile, set the constant mode to 0x1 in the **LDC_CONFIG[7] CNST_MD** bit field.
18. If also using affine transform, set the six affine transform parameters in the following bit fields:
 - **LDC_AB[15:0] A**
 - **LDC_AB[31:16] B**
 - **LDC_CD[15:0] C**
 - **LDC_CD[31:16] D**
 - **LDC_EF[15:0] E**
 - **LDC_EF[31:16] F**
 If affine transform is not used, these must be set to the following values:
 - **LDC_AB[15:0] A = 4096**
 - **LDC_AB[31:16] B = 0**
 - **LDC_CD[15:0] C = 0**
 - **LDC_CD[31:16] D = 0**
 - **LDC_EF[15:0] E = 4096**
 - **LDC_EF[31:16] F = 0**
19. Set the **LDC_PCR[0] EN** bit to 1 to start the LDC operation.
20. Wait for the **LDC_PCR[2] BUSY** bit to become IDLE (0x0) or wait for the end of frame completion interrupt.

9.4.5.4.4 ISS SIMCOP LDC Programming Affine Transformation

Camera motions cause the frames to have translation or rotation differences. The affine transform offers control to account for scaling, rotation, and translation transforms.

For example, the rotation use case can be parameterized with the affine transform parameters shown in [Figure 9-221](#).

Figure 9-221. ISS SIMCOP LDC Parameters for Rotation

$$\begin{bmatrix} \text{hoff} \\ \text{voff} \end{bmatrix} = \begin{bmatrix} a & b \\ d & e \end{bmatrix} \begin{bmatrix} \text{hd} \\ \text{vd} \end{bmatrix} + \begin{bmatrix} c \\ f \end{bmatrix}$$

$$\begin{bmatrix} \text{hoff} \\ \text{voff} \end{bmatrix} = \begin{bmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{bmatrix} \begin{bmatrix} \text{hd} \\ \text{vd} \end{bmatrix} + \begin{bmatrix} h_0 - h_0 \times \cos(\theta) - v_0 \times \sin(\theta) \\ v_0 + h_0 \times \cos(\theta) - v_0 \times \sin(\theta) \end{bmatrix}$$

ldc-016

where theta is the angle of rotation. In the scaling case, the affine transform uses the parameters shown in [Figure 9-222](#).

Figure 9-222. ISS SIMCOP LDC Parameters for Scaling

$$\begin{bmatrix} \text{hoff} \\ \text{voff} \end{bmatrix} = \begin{bmatrix} a & b \\ d & e \end{bmatrix} \begin{bmatrix} \text{hd} \\ \text{vd} \end{bmatrix} + \begin{bmatrix} c \\ f \end{bmatrix}$$

$$\begin{bmatrix} \text{hoff} \\ \text{voff} \end{bmatrix} = \begin{bmatrix} \alpha & 0 \\ 0 & \alpha \end{bmatrix} \begin{bmatrix} \text{hd} \\ \text{vd} \end{bmatrix} + \begin{bmatrix} h_0(1 - \alpha) \\ v_0(1 - \alpha) \end{bmatrix}$$

ldc-017

where alpha is the scale factor. Translation uses an identity matrix with the translation vector as the affine transform parameters, as in [Figure 9-223](#), where Th and Tv are the translation parameters. More complex transforms can be derived and the affine transformation is general so that optimization routines can be used to provide the best parameters to align two frames.

Figure 9-223. ISS SIMCOP LDC Parameters for Translation

$$\begin{bmatrix} \text{hoff} \\ \text{voff} \end{bmatrix} = \begin{bmatrix} a & b \\ d & e \end{bmatrix} \begin{bmatrix} \text{hd} \\ \text{vd} \end{bmatrix} + \begin{bmatrix} c \\ f \end{bmatrix}$$

$$\begin{bmatrix} \text{hoff} \\ \text{voff} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \left[\begin{bmatrix} \text{hd} \\ \text{vd} \end{bmatrix} + \begin{bmatrix} \text{Th} \\ \text{Tv} \end{bmatrix} \right]$$

ldc-018

To initialize and run the LDC to perform affine transform, the application must:

1. Check and wait for the [LDC_PCR\[2\]](#) BUSY bit to become IDLE (0x0).
2. Set the [LDC_PCR\[4:3\]](#) MODE bit field for UYVY (0x0) or NV12 data (0x2).
3. If lens distortion correction is performed at the same time as the affine transform, set the [LDC_PCR\[2\]](#) LDMAPEN bit to 1. Otherwise, set the [LDC_PCR\[1\]](#) LDMAPEN bit to 0.
4. Set the input frame base address in the [LDC_RD_BASE\[31:0\]](#) RBASE bit field. The frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in the [LDC_RD_OFST\[15:0\]](#) ROFST bit field.
6. If reading the input from a circular buffer:
 - Set [LDC_PCR\[9\]](#) CIRCEN = 1
 - b. If using row address, LDC computes the row number and applies a modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in [LDC_RD_OFST.MOD](#). In UYVY mode, the number of rows in the buffer is [LDC_RD_OFST.MOD](#). In NV12 and NV21 modes, the number of rows in the Y buffer is [LDC_RD_OFST.MOD](#) and the number of rows in the Cb/Cr buffers is ([LDC_RD_OFST.MOD](#) / 2).
7. Set the tile size in the [LDC_BLOCK\[15:8\]](#) OBH and [LDC_BLOCK\[7:0\]](#) OBW bit fields. See constraints on OBW in [Table 9-2770](#)
8. Set the pixel pad in the [LDC_BLOCK\[19:16\]](#) PIXPAD bit field.
9. Set the input frame size in [LDC_INPUT_FRAME_SIZE\[29:16\]](#) H and [LDC_INPUT_FRAME_SIZE\[13:0\]](#) W.
10. Set the output frame size in the [LDC_FRAME_SIZE\[29:16\]](#) H and [LDC_FRAME_SIZE\[13:0\]](#) W bit fields. H and W values must be multiples of OBH and OBW, respectively.
11. Set the starting output point in the [LDC_INITXY\[13:0\]](#) INITX and [LDC_INITXY\[29:16\]](#) INITY bit fields.
12. Set the output frame starting address in the [LDC_WR_BASE\[31:0\]](#) WBASE bit field. The output frame must be 16-byte aligned.
13. Set the output frame line offset in the [LDC_WR_OFST\[15:0\]](#) WOFST bit field.
14. If the data format is NV12, set the 4:2:0 UV input plane base address in the [LDC_420C_RD_BASE\[31:0\]](#) RBASE bit field. This address must be 16-byte aligned.
15. If the data format is NV12, set the 4:2:0 UV output plane base address in the [LDC_420C_WR_BASE\[31:0\]](#) WBASE bit field. This address must be 16-byte aligned.
16. Set the mesh offset table pointer to the correct address ([LDC_MESHTABLE_BASE\[31:0\]](#) BASE and [LDC_MESHTABLE_OFST\[15:0\]](#) OFST). Set the table downsampling factor for MxM downsampling in [LDC_MESHTABLE_CONFIG\[2:0\]](#) M.
17. If the LDC is connected to image buffers where the output address is not updated for each tile, set the constant mode to 0x1 in the [LDC_CONFIG\[7\]](#) CNST_MD bit.
18. Set the Y plane interpolation type to bilinear or bicubic in the [LDC_CONFIG\[6\]](#) YINT_TYP bit.
19. Set the six affine transform parameters in the following bit fields:
 - [LDC_AB\[15:0\]](#) A
 - [LDC_AB\[31:16\]](#) B
 - [LDC_CD\[15:0\]](#) C
 - [LDC_CD\[31:16\]](#) D

- [LDC_EF\[15:0\]](#) E
 - [LDC_EF\[31:16\]](#) F
- If affine transform is not used, then these need to be set to the following values: [LDC_AB\[15:0\]](#) A = 4096, [LDC_AB\[31:16\]](#) B = 0, [LDC_CD\[15:0\]](#) C = 0, [LDC_CD\[31:16\]](#) D = 0, [LDC_EF\[15:0\]](#) E = 4096, and [LDC_EF\[31:16\]](#) F = 0.
20. Disable perspective warp transform with [LDC_PCR.PWARPEN](#) = 0. Set the two perspective transform parameters [LDC_GH.G](#) = 0 and [LDC_GH.H](#) = 0.
 21. Set the [LDC_PCR\[0\]](#) EN bit to 1 to start the LDC operation.
 22. Wait for the [LDC_PCR\[2\]](#) BUSY bit to become IDLE (0x0) or wait for the completion interrupt.

9.4.5.4.5 ISS SIMCOP LDC Programming Perspective Transformation

Perspective transforms are used to align the image data of two different cameras viewing the same scene from different positions. It can also be used in the case of stereo image rectification to align the epipolar lines of the left/right image pair with their scanlines.

The following steps need to be performed by the application to initialize and run LDC to perform perspective transform.

1. Check and wait for [LDC_PCR\[2\]](#) BUSY to become IDLE (0x0).
2. Set [LDC_PCR\[4:3\]](#) MODE for UYVY (0x0) or NV12 data (0x2).
3. If lens distortion correction is performed at the same time as the perspective transform, set [LDC_PCR\[1\]](#) LDMAPEN = 0x1. Otherwise, set [LDC_PCR\[1\]](#) LDMAPEN = 0x0.
4. Set the input frame base address in [LDC_RD_BASE\[31:0\]](#) RBASE. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in [LDC_RD_OFST\[15:0\]](#) ROFST.
6. Set the tile size in [LDC_BLOCK\[15:8\]](#) OBH and [LDC_BLOCK\[7:0\]](#) OBW. Note the constraints on OBW in [Table 9-2770](#).
7. Set the pixel pad in [LDC_BLOCK\[19:16\]](#) PIXPAD.
8. Set the input frame size in [LDC_INPUT_FRAME_SIZE\[29:16\]](#) H and [LDC_INPUT_FRAME_SIZE\[13:0\]](#) W.
9. Set the output frame size in [LDC_FRAME_SIZE\[29:16\]](#) H and [LDC_FRAME_SIZE\[13:0\]](#) W. These values must be a multiple of OBH and OBW respectively.
10. Set the starting output point in [LDC_INITXY\[13:0\]](#) INITX and [LDC_INITXY\[29:16\]](#) INITY.
11. Set the output frame starting address in [LDC_WR_BASE\[31:0\]](#) WBASE. The output frame must be 16-byte aligned.
12. Set the output frame line offset in [LDC_WR_OFST\[15:0\]](#) WOFST.
13. If the data format is NV12, set the 420 UV input plane base address in [LDC_420C_RD_BASE\[31:0\]](#) RBASE. This address must be 16-byte aligned.
14. If the data format is NV12, set the 420 UV output plane base address in [LDC_420C_WR_BASE\[31:0\]](#) WBASE. This address must be 16-byte aligned.
15. Set the mesh offset table pointer to the correct address ([LDC_MESHTABLE_BASE\[31:0\]](#) BASE and [LDC_MESHTABLE_OFST\[15:0\]](#) OFST). Set the table downsampling factor for MxM downsampling in [LDC_MESHTABLE_CONFIG\[2:0\]](#) M.
16. If LDC module is connected to image buffers where the output address is not updated for each tile, set constant mode = 0x1 in [LDC_CONFIG\[7\]](#) CNST_MD.
17. Set the Y plane interpolation type to bilinear or bicubic in [LDC_CONFIG\[8\]](#) YINT_TYP.
18. Set the eight perspective transform parameters in the following bit fields:
 - [LDC_AB\[15:0\]](#) A
 - [LDC_AB\[31:16\]](#) B
 - [LDC_CD\[15:0\]](#) C
 - [LDC_CD\[31:16\]](#) D

- [LDC_EF\[15:0\]](#) E
- [LDC_EF\[31:16\]](#) F
- [LDC_GH\[0:15\]](#) G
- [LDC_GH\[31:16\]](#) H

. If affine transform is not used, then these need to be set to the following values: [LDC_AB\[15:0\]](#) A = 4096, [LDC_AB\[31:16\]](#) B = 0, [LDC_CD\[15:0\]](#) C = 0, [LDC_CD\[31:16\]](#) D = 0, [LDC_EF\[15:0\]](#) E = 4096, [LDC_EF\[31:16\]](#) F = 0, [LDC_GH\[0:15\]](#) G = 0 and [LDC_GH\[31:16\]](#) H = 0. Enable [LDC_PCR\[7\]](#) PWARPEN = 1.

19. If smart codec statistics are desired:

1. Enable by setting [LDC_PCR\[8\]](#) SCSEN = 1.
2. Set the number of regions in [LDC_SCS_CTL\[6:5\]](#) REGION (0=1x1, 1=2x2, 2=3x3, 3=4x4).
3. Set the division factor for the sum and sum of squares statistics in [LDC_SCS_CTL\[4:0\]](#) ACCSHIFT. The division is a power-of-two division, so this value is the right shift parameter.
4. Program the number of lines computed before the row macroblock statistics are transferred to memory in [LDC_SCS_CTL\[29:16\]](#) SLICE_SIZE. This feature is useful for slice-based processing to ensure that statistics for the macroblock rows are available at the same time that the LDC output data is available. This must be a multiple of 16.

20. Set [LDC_PCR\[0\]](#) EN = 0x1 to start the LDC operation.

21. Wait for [LDC_PCR\[2\]](#) BUSY to become IDLE (0x0) or wait for the end of frame completion interrupt.

9.4.5.5 ISS SIMCOP LDC Register Manual

9.4.5.5.1 ISS SIMCOP LDC Instance Summary

Table 9-2773 summarizes the LDC instance.

Table 9-2773. LDC Instance Summary

Table 9-2777. LDC_PCR

Address Offset	0x0000 0004	Instance	LDC
Physical Address	0x4222 0104		
Description	LDC Peripheral Control		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								STANDBYMODE	RESERVED				SCS_SUPPORT	AFF_EXPANDEN	CIRCEN	SCSEN	PWARPEN	BMODE	MODE	BUSY	LDMAPEN	EN									

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved.	R	0x0
17:16	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0 FORCE Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 0x1 NO No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 0x2 SMART Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.	RW	0x2
15:12	RESERVED	Reserved.	R	0x0
11	SCS_SUPPORT	Reports '1' if SCS feature is supported by LDC.	R	0x0
10	AFF_EXPANDEN	Enables expanded format of affine warp coefficients (A, B, D, and E). 0: A, B, D, E are treated as S14Q12 1: A, B, D, E are treated as S16Q12	RW	0x0
9	CIRCEN	Enables circular addressing mode. 0 - Disable circular addressing for input data. 1 - Enable circular addressing.	RW	0x0
8	SCSEN	Enable/Disable smart codec statistic (SCS) function. 0 - Disable SCS 1 - Enable SCS	RW	0x0
7	PWARPEN	Enable perspective warp transform. Set to 1 to enable use of LDC_GH[15:0] G and LDC_GH[31:16] H.	RW	0x0
6:5	BMODE	Bayer data format (only applicable when MODE=1). 3: A-law data in/out, 2: Packed 8-bit data in/out, 1: Packed 12-bit data in/out, 0: Unpacked 12-bit data in/out	RW	0x0
4:3	MODE	2: YCbCr 4:2:0 Lens Distortion, 1: Bayer chromatic aberration mode, 0: YCbCr 4:2:2 Lens Distortion	RW	0x0
2	BUSY	Idle/busy status, 0: Idle, 1: Busy, asserted when function is started, cleared when function is complete	R	0x0

Bits	Field Name	Description	Type	Reset
1	LDMAPEN	LD Mapping Enable, 1: Enabled, 0: Disabled	RW	0x0
0	EN	Write 1 to start the function, as specified in MODE	RW	0x0

Table 9-2807. LDC_SCS_CTL

Address Offset	0x0000 0054	Instance	LDC
Physical Address	0x4222 0154		
Description	Define number of regions and output divider for region based statistics.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED		SLICE_SIZE										RESERVED							REGION	ACCSHIFT											

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Reserved.	R	0x0
29:16	SLICE_SIZE	Sets the number of output lines computed by LDC before the computed macroblock row statistics are transferred to system memory. This must be a multiple of 16 so bits [19:16] are internally fixed to zero. The maximum possible value is 8176 (0x1FF0).	RW	0x0
15:7	RESERVED	Reserved.	R	0x0
6:5	REGION	Sets the number of regions in both directions for the region based statistics. Possible values: 0 - 1x1 1 - 2x2 2 - 3x3 3 - 4x4	RW	0x0
4:0	ACCSHIFT	Sets the output divider for sum of pixels in a region and sum of squares of pixels in a region. This parameter right shifts the final accumulator prior to writing the output statistics.	RW	0x0

Table 9-2811. LDC_MESHTABLE_BASE

Address Offset	0x0000 005C	Instance	LDC
Physical Address	0x4222 015C		
Description	Read address for mesh offset table.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BASE																															

Bits	Field Name	Description	Type	Reset
31:0	BASE	Read address for mesh offset table. (Must be 16-byte aligned so four LSB are coded to 0)	RW	0x0

Table 9-2813. LDC_MESHTABLE_OFST

Address Offset	0x0000 0060	Instance	LDC
Physical Address	0x4222 0160		
Description	Defines the stride between rows for the offset table (in bytes).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																OFST															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved.	R	0x0
15:0	OFST	LDC Mesh table line offset, must be 16-byte aligned so internally [3:0] bits are hard-wired zero.	RW	0x0

Camera Interface Subsystem

This chapter describes the Camera Interface Subsystem (CAL and CSI2_PHY) in the device.

[New DRA7xxP feature versus DRA75x/DRA74x]

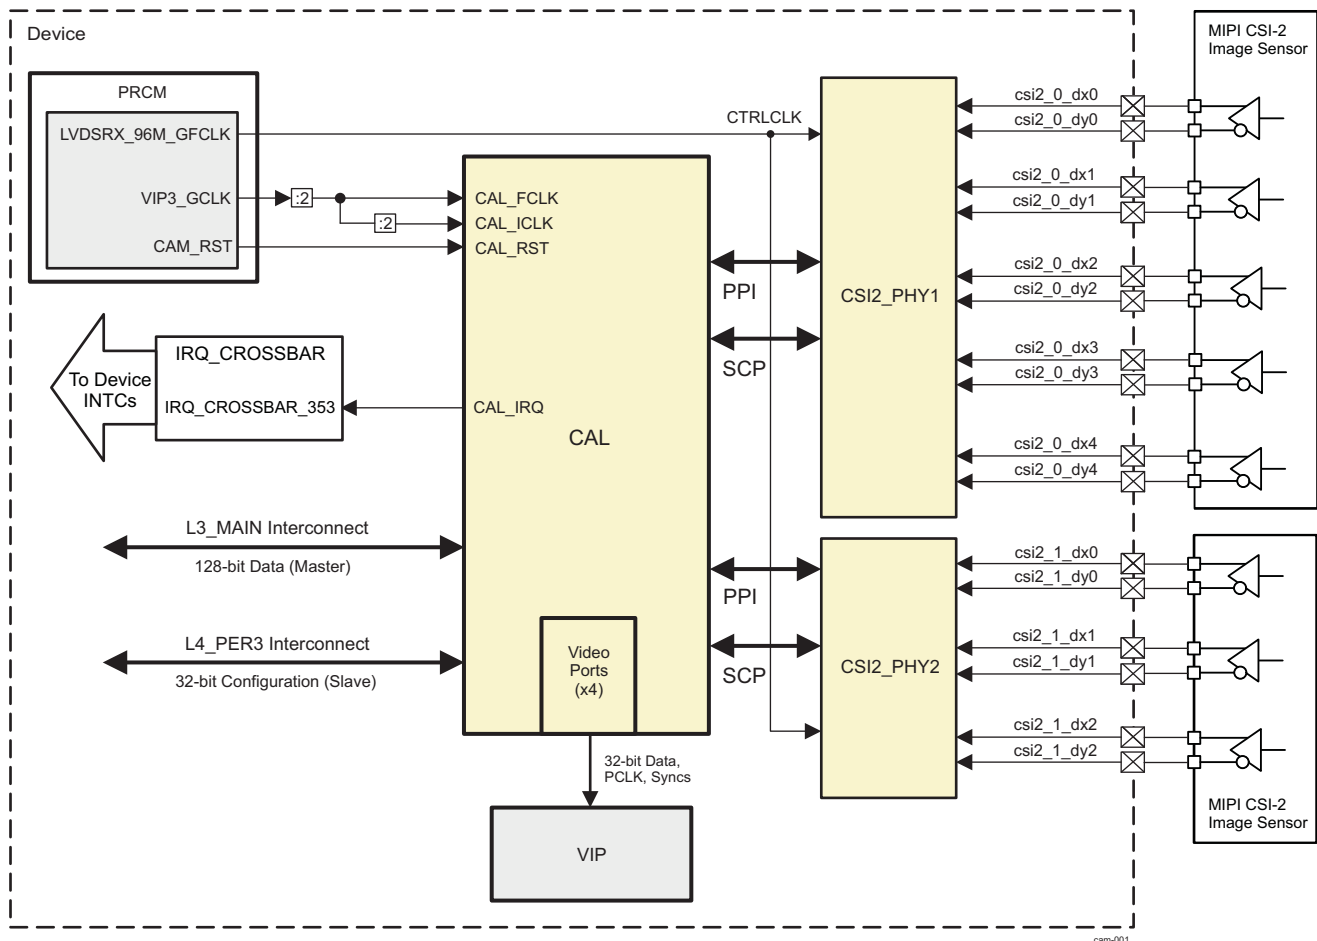

Topic	Page
10.1 CAMSS Overview	3282
10.2 CAMSS Environment	3284
10.3 CAMSS Integration	3286
10.4 CAMSS Functional Description	3289
10.5 CAMSS Register Manual	3331

10.1 CAMSS Overview

NOTE: CAL and CSI2_PHY support is device part number dependent. Refer to a device-specific Data Manual, for more information.

10.1.1 CAMSS Block Diagram

Figure 10-1. CAMSS Overview

10.1.2 CAMSS Features

The device CAMSS provides:

- Camera Adapter Layer (CAL) module with up to 304 MHz processing clock rate
- CAL interfaces:
 - Two PHY Protocol Interfaces (PPI) to MIPI D-PHY compliant receivers (CSI2_PHY1 and CSI2_PHY2)
 - Byte clock for data transfers up to 187.5 MHz (that is, D-PHY with 1.5 Gbps per lane)
 - Programmable clock and data lane position
 - Serial Configuration Interface (SCP)
 - 32-bit slave configuration interface (OCPC) to the L4_PER3 interconnect
 - 128-bit master data interface (OCPO) to the L3_MAIN interconnect and system memory
 - Video port:
 - Four video port interfaces

- Up to 2 pixels per clock cycle
- Pixel rate smoothing buffer
- On-the-fly functional mode: A byte stream received from a PPI is interpreted as a CSI-2 stream. Pixels are extracted and sent to the system memory and/or video port
- MIPI CSI-2 low level protocol support:
 - Up to 8 contexts (VCT + DT combinations)
 - Data lane merger
 - Error detection / correction (CRC/ECC)
 - Re-synchronization FIFO
- Up to four [4] independent pixel processing contexts:
 - All primary and secondary MIPI CSI-2 formats supported
 - Extract pixels from byte stream
 - DPCM decompression (4 pixels/cycle for predictor1; 1 pixel/cycle for predictor2)
 - DPCM compression (2 pixels/cycle for predictor1; predictor2 is not supported)
 - Pixel packing into a byte stream (for memory storage)
- Up to eight [8] independent write DMA contexts:
 - Write header, pixel, or attribute data
 - Horizontal cropping
 - Pack data from independent streams into efficient OCP transactions
 - 1D and 2D addressing modes (only INCR bursts)
 - Resynchronize on line boundaries (for TxBuffer overflows)
 - Linear, circular, and sub-sampled addressing modes
- Unsupported features of the CAMSS:
 - The CAMSS does not have a power switch, making the power domain (PD_CAM) Always-On. For more information on the power domain, see [Section 3.7.14](#), *PD_CAM (Physical PD_COREAON) Description*.

10.2 CAMSS Environment

NOTE: CAL and CSI2_PHY support is device part number dependent. Refer to a device-specific Data Manual, for more information.

This section describes the CAMSS application fields from an environment point of view (external connections). It describes the CAMSS connectivity options and lists all possible interfaces.

10.2.1 CAMSS Interfaces Signal Descriptions

Figure 10-2. CAMSS Environment

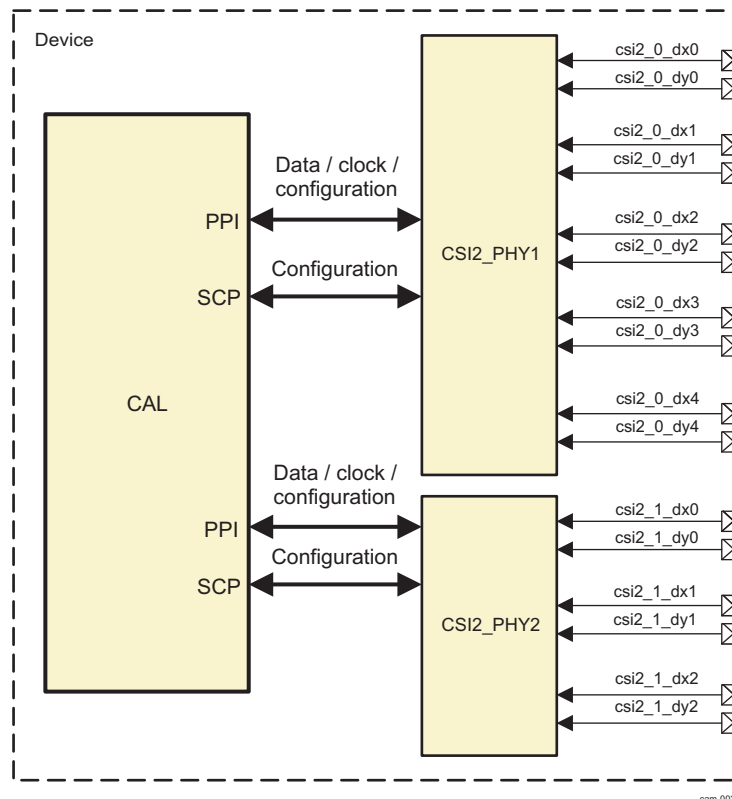

Table 10-1 summarizes the CAMSS I/O signals.
